It uses a cascoded pair of 2N5486 or 2N5485 JFETs, driving a 2N3904/2N3906 buffer, and takes +/-15 VDC supply voltage.

I suspect that its bandwidth might be improved by using faster bipolar-buffer transistors (maybe MPSH-something-or-other) and possibly J310 or U310 JFETs for the front end.

Check out the AADE meter (www.aade.com) - it's the least expensive decently-accurate meter system I know of. I understand it's a kitted version of a project described in an electronics or radio magazine a few years ago (I don't know where the article appeared). A complete schematic is in the manual, which can be downloaded from AADE's site. The kit is (in my opinion) extremely well thought out; the meter I built went together in about an hour, worked first time, and behaves just as AADE says it should. *Very* nicely done.

The little-or-no-extra-equipment approach would be to wire up your varicap arrangement in an oscillator circuit, resonating against a well-known inductance, and measured with a frequency counter or oscilloscope. Getting good accuracy in the face of all of the unknown parasitic reactances of such a circuit is going to be a huge headache, though.

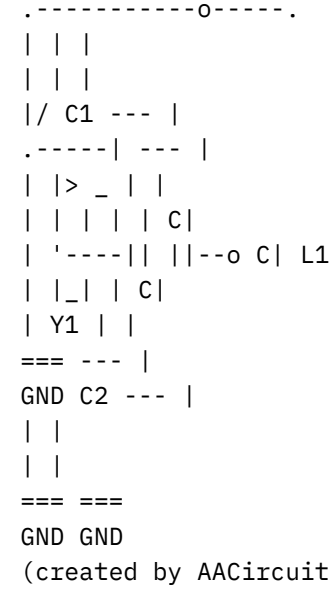
The Pierce circuit is, I believe, only useful for crystals, and not too useful at that.

The Colpitts will definitely want to see you using the thing in parallel mode -- basically you're replacing an inductor with the crystal.

Check out the UHF experimenter's manual from the ARRL. The circuit that they recommend has as it's core a basic grounded-base Colpitts, with the wire from the feedback capacitors to the transistor emitter replaced by the crystal:



(created by AACircuit v1.28.6 beta 04/19/05 www.tech-chat.de)

I don't remember the biasing (obviously this ain't going to work as is) or where you take off your signal, but the idea is that L1, C1 and C2 form a regular old Colpitts at Y1's 3rd-overtone frequency. Y1 just makes sure that the dang thing doesn't drift. What little work I've done with the thing shows it to be very reliable about staying on frequency and starting and all that cool stuff.

Thank you, sir, I appreciate the information, but I've got a list of repeaters from Vancouver up to Anchorage. I've also got a list of repeaters in Northern California, and I know for a fact that I could monitor 90% of them for days on end without hearing anybody. What I wanted most of all was a list of GOOD repeaters, ones with activity on them, between Vancouver and the border of Alaska. I'll worry about Anchorage when I get there.

How about it; any recommendations for "good" repeaters?

Jim

Dave,

Thanks for the tip. I don't want to purchase an entire book for one
circuit though.

I do have some BF998 Dual Gate Mosfets, maybe I can make up a circuit
based on these.

I need around 1pF input capacitance and 1 Meg Ohm, Frequency up to a
couple of hundred MHz.

Regards

David

Looks like I picked a poor example.
The schematic is permanently confidential.
Click on the word "Detail" for the second entry.
Click on the "mail slot icon" for any of the
documents to display the document.
If you click on the word "Summary", it will
show which documents are "Permanently Confidential" in the
column of the same name.

Well Jim, this is way off topic for this newsgroup but I don't think on any 2M repeater, except those in very large cities, will you find too much activity. AFAIAK 2M repeaters are "ham radio telephones". Most of the time folks call only those they know and talk to only those they know. A bit of a "club" thing really.

I have never found 2M to be much good on the road except for the odd occasion - much prefer mobile HF CW and have had MUCH better luck getting QSO's going doing that than I ever did while travelling with my VHF rig alone. For what it's worth - just my opinion.

Also, as you know the population density in Canada, especially northern Canada is significantly less than in the USA so there will always be less activity than you may be used to.

Cheers....Larry VE7EA

John,
It's hard to tell exactly what you have from a verbal description, but I have a suggestion for a test you can make.

Basically, the crystal will look like a small resistance of about 50 ohms or so at its series resonant frequency. Replace the crystal with a 50 ohm resistor (of course, do what you have to do to preserve the DC bias) and see if the circuit oscillates and can be tuned through the crystal frequency. If it doesn't oscillate, chances are that your circuit won't work with a series mode crystal.

Also in general, if you are using a tapped-capacitor colpitts circuit, you can remove the connnection from the junction of the two capacitors to whereever it was connected, and replace that connection with the resistor. If that works, it should oscillate when you replace the resistor with the crystal.

Joe

==========
The quality of any repeater is determined by the (content)quality of
YOUR communications. If you make an effort to activate and are willing
to have a sensible communication/discussion ,it will be a GOOD repeater.

In this respect ,sadly, a number of repeaters are not so good ;))

What I have found for the "farmland" repeaters is they are not amenable to entertaining travelers.
Emergencies - yes. Recommend a restaurant - sometimes. Want to talk about crop disease and prices -- they will talk for hours.

Hint - put a YL on the mic -- that will draw out some responses (;-)
--
CL -- I doubt, therefore I might be !

These specs are probably rather optimistic, in my opinion. I would probably consider something like a large resistor in series with the input of a cascode amplifier (cascode chosen to reduce effective input capacitance due to feedback). Or perhaps a resistive voltage divider, rather than just a series resistor, in an attempt to get flat response over frequency. But there really is no such thing as a 1 Meg resistor at VHF. The stray capacitance across resistors limits the maximum achievable impedance to perhaps tens of kilohms.

However, I'm not expert on such circuits. You might try posting the question to sci.electronics.design. There are some very clever electronic designers there (along with a number who get their jollies from insulting others).

Hi Mitchell,

The 8875 is its own beast... but you can find them surplus from
guy who mod their original Dentron Amplifiers out. I have a 2500
that I'll some day rebuild with a different tube so who knows... I
may even sell my used tubes on ebay.

You can also post a want over on the yahoo rfamplifiers group,
which is a pretty large group about both rf and audio amplifiers...

http://groups.yahoo.com/group/rfamplifiers/

and the group does both tube and solid state amplifiers...

cheers,
skipp

The "totem pole" follower (a FET source follower with a matched FET as the source "resistor") was widely used by Tektronix. It provides flat, near unity gain over a very wide bandwidth, with high input resistance and low input capacitance. It would be very difficult to make a cascode amplifier with response that flat.

The 1 meg ohm resistor is to establish the DC and low frequency impedance. The unavoidable shunt C from the FETs and other sources makes it immaterial at high frequencies. I agree that 1 pF is optimistic -- it would be very difficult to achieve. You would probably have to do some bootstrapping to reduce the C to that level, if you can do it at all, and bootstrapping becomes more difficult as frequency increases.

During my 1996 trip to Inuvik I had quite a list of repeaters along our route. Up and back, I was in Canada for about 26 days. In that time I think I got TWO responses via 2-meter :-)

Hi there:

I am looking for resources to obtain schematics, pc layouts and such
for solid state RF amplifiers. I am interested in everything from 6 meters
up to 432 MHz.

I know there is someone that advertises in QST but the May issue of
this year did not have them in the advertising section.

I am looking for amps that work off of 13.8 volts and anywhere from
100 watts up to about 150 watts output. Any information that you might have
would be greatly appreciated.

3200. ferrite toroids and capacitors for antenna tuner

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-06-13 09:26:58 UTC
From: John Laczik <John@laczik.org>
Message-ID: <e6m0d2$aq0$1@news.ox.ac.uk>
Source record: 11651

Which types of ferrite toroids and capacitors would be recommended
for an antenna tuner that is to be used 1.5 MHz - 30 MHz (possibly
up to 50 MHz)? Max. transmit power is 100 ~ 150 W.

Ideally I would prefer components that are available from either
RS (rswww.com) or Farnell (uk.farnell.com).

Farnell do toroids from N27, N30, 3C85, 3R1, 4C65, 3E5 and 3E25
materials; which ones are suitable for broadband HF power applications?

For the capacitors, would any of the surface mount types be suitable?

Thanks,

John

Exactly what "broadband HF power application" do you have in mind? A single transformer or balun covering the whole band? Capacitors are usually avoided in broadband applications. How will you be using them?

Are you a licensed amateur?

Roy,

> Exactly what "broadband HF power application" do you have in mind?

Sorry, I should have been more precise. What I wrote referred to an antenna tuner that covers the various ham/marine bands in the 1.5 MHz to 50 MHz range, i.e inductors and capacitors that are suitable for use in this 'broad' frequency range. Also, the antenna tuner probably will have a balun in it, which would not be tuned and hence would be broadband.

> Are you a licensed amateur?

Yes.

> How will you be using them?

I am trying to set up a rig on a boat, and one of the options is to make a remote controlled antenna tuner for RX, and up to ~100W TX, instead of using one of the rather expensive commercial units. The antenna/tuner will be used to receive marine weather transmissions, and for CW QSOs on the ham bands.

Thanks,

John, HA5PG/MM

Don't think it is really necessary to use (ferrite) toroids for a
compact 100W capable HF antenna matching unit.
Depending on type of antenna a simple variable capacitor(s) /variable
roller inductor unit will highly likely do the trick, even if remotely
operated.
If the unit needs to have a balun ,you obviously want to use a balanced
feeder, but it is doubtful that an exposed balanced feeder in a 'salt
spraying environment' will be effective.

Thanks for the clarification. The core requirements for a broadband application like a broadband transformer or balun are much different than for a narrowband (high Q) application like an inductor in a matching network.

I wouldn't use ferrites at all for the inductor cores, but powdered iron -- type 6 except perhaps below 3.5 MHz where type 2 might be slightly better. For fixed capacitors I'd stick to NPO (C0G) ceramic for Q and stability.

3208. Tektronix FG501A drift question

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-06-14 03:01:22 UTC
From: hexter@blazenet.net
Message-ID: <YuednVBq6_uf4RLZnZ2dnUVZ_tKdnZ2d@suscom.com>
Source record: 11659

Hi folks,

I have a Tek function generator model FG501A and the D.C. offset in the 'fixed' or 'non-variable' position seems real drifty with temperature changes. I thought my unit was bad when I noticed it was offset nearly .5 volts at startup then drifting toward 0 offset after extended warmup, that was until I discovered the unit where I work was even worse than mine at about 1.5 volts of offset. The offset can be adjusted to zero for some exact given temperature, but geez guys, change the temperature about 10 degrees and the offset changes about .25 volts.

Anyone ever run into this? Seems kinda crappy compared to most Tek stuff. Do the two units I can lay my hands on have a shot compensating component? Other than d.c. offset drift the unit works perfect.

Thanks.

3211. On measuring small coils

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-06-14 18:09:25 UTC
From: K7ITM <k7itm@msn.com>
Message-ID: <1150308565.001491.278920@h76g2000cwa.googlegroups.com>
Source record: 11662

Hi all,

I'm in the midst of winding a bunch of little coils on ferrite toroids, and was pondering how to measure their inductance and adjust it (by changing turns spacing around the toroid) to the desired values. I have an HP4274A LCR meter, but its test frequency only goes up to 100kHz, and I wanted to measure the coils closer to their ~10MHz operating frequency. It occured to me that I could make the measurement with a one-port network analyzer measurement. If I resonate the coil with a capacitor of known value (C1) with one end of that tank grounded, and put another capacitor (C2) in series from the top of the tank to the VNA port, and a third capacitor (C3) shunt across the VNA port, by adjusting C2 I can get "perfect" return loss at some frequency. When I do that, the values of C1, C2 and C3, and the frequency at which the return loss is infinite, will tell me not only the inductance but also the Q at that frequency.

I guess I can write a general expression for the impedance the VNA sees, in terms of C1, C2, C3, L and Rseries, and the frequency, and set that equal to 50 ohms, plug in the capacitor values, and calculate L and R. But for now I'm just using an easy RFSim99 model, with the inductor "physical model" selected so I can set Q and frequency at which Q is applied. I just set the capacitances as they are in my measurement circuit (with C2 estimated from the rotation angle of the little air trimmer I'm using there), and adjust the coil inductance and Q in the simulation till the return loss null is deep and the frequency matches the observed VNA frequency for that null.

My coils are on T-25-6 cores, around 1uH, and I'm using 180pF for C1, 150pF for C3, and can vary C2 from about 12 to 30pF. Even with my crude reading of C2, I can determine the Q within 10% tolerance, which is plenty accurate enough for my work. This same method should work well for coils over a pretty wide range of Q, inductance and operating frequency, so long as you have capacitors with Q much higher than the coil (or known capacitor Qs), and the parasitic reactances around the circuit are not out of control.

Lest you think a VNA is out of your reach, check out ebay auctions and the very nice homebrew VNA described at http://users.adelphia.net/~n2pk/. It can be a very useful piece of equipment for an RF homebrewer.

Cheers,
Tom

w9gb-

Do you by any chance have a Fluke collection as well?

I'm looking for an instruction sheet for installing the 1300 MHz
prescaler, Option 72XXA-331K, into the Fluke 7260A or 7261A counters. It
is Fluke Stock Number 546087. Fluke no longer had any record of it when I
checked.

BAMA has the 7261A manual, but not this instruction sheet.

Thanks.

I am trying to build a set of filters for the ham bands for use with the 600W motorola designed fet amplifier described in last months qsl.I have sucessfully modelled suitable filters using pspice using 3 series inductors with 2 parallel caps for each band but I notice the current in the caps can be several amps peak. Values range from 150 to 3000pf. Can Ceramics be used? Or do I need several parallel silver mica caps? How much power can one dissipate in these caps? Near the corner frequency there is as much as 6db gain under low load conditions and this exacerbates the problem. I could move the corner further up so that the filter is not excited at the peak current, but then I will probably have to increase the number of poles to 7 from 5 to get enough attenuation at the third harmonic. Is there a better filter architecture that minimizes cap current?

Source record: 11666

John,

I designed some automatic tuners on the market. It was a very lengthy process in selecting components and laying out circuit boards. It really is a much better value to just buy one, unless you want to learn how to design a tuner.

You probably want powdered iron mixes for low frequencies (larger inductor values) and air core coils for small values.

The capacitors would have to be silver mica types although you might find some high current high Q multi-layer ceramics that will work. There is no reason to go much over the contact voltage breakdown of the relays when picking capacitor voltage, since the relay would fail first. Current is another issue. You must obtain capacitors that handle high current, meaning the capacitor must have low ESR. As a general rule that would mean a snubber mica capacitor or a multi-layer HV chip capacitor.

Relay selection is critical. I cut dozens of relays open looking for good candidates, and then HV tested and RF tested the relays for breakdown voltage. A DC test will not work.

It's pretty tough to build an automatic tuner that will handle 100 watts or more into a wide range of load impedances. Most of the problem is parts selection and board layout.

This comming Sunday...

+++ Now even more Buyers Parking !!!
Thanks to TKT we have use of their new parking lot
across Albany St from the SWAPFEST !!!

!! ** More Buyers PARKING is available ** for details see
http://web.mit.edu/w1gsl/Public/flyer

*** !!!! In our Traditional GARAGE and the adjacent lot !!!! ****
so come rain or shine or super heat the Flea is on !!!

********* $1 buyers discount with hardcopy of this notice ********

COMPUTERS - ELECTRONICS - HAM RADIO - COMPUTERS - ELECTRONICS - HAM RADIO

FLEA all SUMMER at MIT
Sunday June 18yh 2006
9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take
place on the third Sunday of each month this summer,
April thru October.

There is tailgate space for over 600 sellers and
free, off-street parking for >2000 cars!

Buyers admission is $5 (you get $1 off if
you're lucky enough to have a copy of our ad)
and sellers spaces are $20 for the first and
$15 for each additional at the gate.

The flea will be held at the corner of Albany and
Main streets in Cambridge; right in the Kendall
Square area from 9AM to 2PM, with sellers set-up
time starting at 7AM.

SEASON PASS + Advance Seller Discount

A sellers discount season pass is available which
offers a 30% discount. By prepaying you get a
discount and earlier admission. See the registration form.

*** Attention Sellers ***
Prepaid vendors.. Season Pass or monthly,

will be admitted FIRST.
Separate lines will form prior to gate opening
for prepaid and nonprepaid vendors

!! RAIN or SHINE !! Have no fear of rain, a covered
well illuminated tailgate area is available for all
sellers (6'8" clearance).

Talk-in: 145.23- (PL 88.5) W1BOS/R and
W1XM/R-449.725/444.725 (PL 114.8/2A).

Sponsors: MIT Electronics Research Society
MIT UHF Repeater Association (W1XM)
MIT Radio Society (W1MX)
Harvard Wireless Club (W1AF)

Source record: 11668

Have a look at http://www.avxcorp.com/docs/catalogs/hi-q.pdf -- there
are likely other manufacturers who have lines of high current RF caps,
too. The caps in the referenced PDF are rated for max current about
15A at 150pF, 13MHz; 11A at 150pF, 64MHz; over 20A at 3000pF at 13MHz.
High enough for you? Parallel a couple if not! These are SMT-style
ceramics--a 3300pF 1000WVDC will be 9.4mm long, 9.9mm wide, 3.3mm max
thick. A 150pF 3000WVDC will be 5.8mmx6.4mm, max 3.3mm thick. (Those
are the only two len * width in that series.)

Cheers,
Tom

If you can, get a copy of the book " Radio Frequency Transistors" by
Norm Dye & Helge Granberg. There is a chapter specifically about
designing and building Filters to handle the output of Motorola based
transistor RF amplifiers. To quote from the book:
"Paralleling of multiple capacitors provides a means to increase
current carrying capabilities and allows the use of inexpensive disc
types.
.....Typically the RF voltage ratings of such capacitors are
approximately 30-35% of their D.C. voltage ratings."
High voltage ceramic disc caps are widely available (1,000 to 3,000
volts).
The book also has formulas for calculating various types of filters,
estimating RF currents and voltages, and choosing components, etc.
Highly recommended!

Jeff

Thanks, Tom for the input. I looked up the AVX caps and they would do
the job, but I find them difficult to get. They seem not to be in stock
anywhere at retail, and are quoted at 11 weeks leadtime. Somewhere
there must be a supplier who caters to small quantity orders I would
think. I just haven't found them!

Thanks Jeff for the information. However I think it is dielectric loss
and not working voltage that may give me trouble here. Even with 3kV
disc ceramics the loss is quoted at 2% so these will get hot at a few
amps. The low loss AVX hi-q ceramics do appear to be better but are not
east to find. I am new to amateur radio so just learning these things.
I did order the book you suggested. Thanks,
Paul.

American Technical Ceramics (ATC) makes capacitors specifically for high power, low loss RF applications. You might see if you can get some of their products.

My guess is that you'll find ordinary NPO ceramics to be good enough if you use multilayer ones, rather than disks, of decent physical size. The critical spec is the ESR if you can get it for candidate ceramics. I don't, however, have personal experience at running them at this power level.

3230. Looking for DC over coax injector design

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-06-16 09:40:58 UTC
From: zorton <zorton@jtan.com>
Message-ID: <1150450858.458876.257340@i40g2000cwc.googlegroups.com>
Source record: 11681

One of my local projects here is going to be installing a ground rod and service box for the shack. I scrounged an old outdoor weatherproof box that will work great with one exception; it has a large meter shaped hole in the front that i'll have to cover up with some steel or plastic.

While poking at it with my brother in law the idea of using plexiglass to see inside was brought up. Of course all this box will do is provide a junction for the RF and ground and house my lighting arrestor. However, it wouldn't be like me to not install some blinky lights!

Here's the idea. Since the lightning arrestor will pass DC except when it's shorted to ground I was thinking of putting 12 volts up past the arrestor and lighting up a green led or something. That way all I have to do is look at the box to know that the arrestor isn't shorted to ground.

Is there a nice DC coax injector design floating around? I'm starting to think that once I get 12 volts out to the box i'll end up adding more and more stuff as well. How about a nice red light that lights up when i'm transmitting... :)

Thanks and 73,
Justin KL1RL

If you put DC injection somewhere between the arrestor and your rig
and feed power to the DC injector from any convenient mains outlet,
this may cause a lot of harm.

Assume that the lightning will cause some high voltage peaks in the
mains that will propagate through the DC injector and destroy the
input stages of your rig. If the overvoltage is really large, the
lightning arrestor will limit the amplitude _at_the_arrestor_, but if
the injector is close your rig, your rig will receive a higher voltage
than the arrestor turn on voltage, due to the cable voltage loss
between the injector and arrestor.

You will also need a separator in the arrestor box to separate RF and
the LED DC current from each other, otherwise, the LED will rectify
your transmitted RF current and cause a lot of harmonics, which will
radiate through the antenna.

Note also that the separator filter inductances in the arrestor box
might interact with the lightning pulse and might even generate larger
voltages than otherwise.

But to your actual question, for HF+6m any LC filter circuit should be
doable, as long as you keep an eye on stray inductances and
capacitances.

On VHF/UHF a single band injector/separator could be done from
open/closed quarter/half wave stubs.

BTW, in the "RF Transistors" book, on page 103 there is a photo of a large RF Power Amplifier that has 6 filters built using large Ceramic Capacitors & Toroid forms.
Quote: ".... a 2KW prototype RF amplifier for a period of ten years with over 5000 hours of operation without failure."

Andy writes:

The conventional way is to use a DC blocking cap, an RFC as
an injector, and a resistor as a current limiter (in series with the
RFC in case the line becomes shorted at the output)

If you think of a "worst case", there are possible problems, like,
if lightening strikes your antenna, or whatever..... You cannot
protect everything from every possible occurrence however, and
should realize your risk and weigh what can "possiblY" happen
aainst simplicity of design..... as every manufactured radio does...

A couple hints ; make the RFC just large enought wire size to act
as a fuse and put a big-ass (and I mean enough big-ass to sink
enough current for long enough to burn out the RFC in case of a
strike) capacitor on the DC supply side.....1000uf, for instance

Stick a neon bulb across the coax (if it is receive only). A big
transient will make a really good short, instantly, and help a lot....

Make your own spark gap on the coax with maybe .010 separation
by epoxying a couple of #22 wire together. This will be a cheap and
easy "spark gap".....

But you CAN'T protect against everything..... It is purely a
risk
assessment, and a direct stike will ALWAYS wipe you out..... A nearby
strike, however, can be shunted or opened.....

And, you can unplug your receiver, (or whatever) from the coax
when not in use by using a series coaxial protection relay.,...It
connects your shack to the antenna whenever you power up.....

Just a couple of ideas..... Don't get carried away with this, cause
there
is never anything more than a bunch of tradeoffs....

Justin,
Wow! Paul really has concerns. Some I don't quite understand. The rig is connected to the antenna anyway, so if lightning zaps it, a well done DC injector shouldn't make things any worse that it already is. My opinion is that if you get a hit bad enough to go from the mains, into the injector and into the rig, you'll have lots of damage from other pathec as well, so this probably won't be the worst, ot even the only thing to zap the rig. Where you inject the DC into the line, you have an RF choke. Appropriate attention to both RF and arc-over considerations should minimize this as a "damage-to-the-rig". The capacitor used to block the DC from the rig, must be minimum size needed (for the lowest band you'll use) so it passes the least amount of lightning-induced spike.

I don't see any serious Gotchas, but then, I don't know your capability / technical level, but two RF choke and and two caps is all it takes, while you observe all the "normal" RF care required for a box through-which you are routing RF...short leads, proper connections to the arrestor and all that. The lightning arrestor, obviously can't be a DC short to ground or you need the cap on the rig side and take the DC off on the rig side of the arrestor. If the arrestor passes DC, you can pick off the DC on the antenna side.

On the "DC" side of the choke, you should also have another bypass cap to keep RF off the LED and out of the 12 V power source.

I think the most important thing in this whole situation, is to do the arrestor correctly. A good installation is fairly complex and the closet to the ideal the more protection you'll get.

THE DC part should be pretty standars practice. Short leads where ther need to be. Big gaps where any high voltage can be. Super-duper ground for the arrestor. Proper RF practices.

73, Steve, K9DCI

Drive he neighbors nuts with these blinking lights in the back yard!

You could even rectify the RF and then the little blinkey lights'll blink with your SSB or CW...

Later Dude.

3235. Think you might be interested? Then here's your FAQ!

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-06-16 19:22:26 UTC
From: Brian's Conscience <radio.ham@lycos.co.uk>

A necessary preface.....

(It is becoming increasingly difficult to fly the flag for
decency and for civilised behaviour in Radio Hammery. Even
the Usenet newsgroups dedicated to the cause have degenerated
into a hotbed of abusive onslaughts by those who ought to know
better; the Nugatory Numpties who boast of an interest
exceeding 10, 20, 30, 40 or even 50 years and yet who have
proved themselves incapable of even meeting the trivial exam
standards set for 6-year-olds. However, there still exists
the fundamental basis on which Ham Radio is based, and
that will never die. This FAQ ("What Is Ham Radio?") will
be regularly published and will not be shouted or bullied
down. It is important that those of a technical bent, who
are the natural seed-corn of Radio Hammery and who
gravitate towards us to be the real novitiate, can
still find us, (and know that we are still here), their fellows.)

-----ooooo-----

So,.....What is Ham Radio?

Ham Radio is a technical pursuit for those who
are interested in the science of radio wave
propagation and who are also interested in the
way that their radios function. It has a long-standing
tradition of providing a source of engineers who
are born naturals.

Ham Radio awakens in its aficionados a whole-life
fascination with all things technical and gives
an all-abiding curiosity to improve one's scientific
knowledge. It's a great swimming pool, please dive in!

This excitement causes a wish to share the experience
with ones fellow man, and shows itself in the
gentlemanly traditions of Ham Radio.

Radio Hams are in a unique privileged position in that
they can construct and operate their own equipment! No-one
else has this privilege. Users, such as broadcasters,
the po lice and armed farces, CBers and mobile phone
users have to purchase ready-made gear. Manufacturers
are not licensed to operate their gear. Radio Hams
are qualified to design, build and then

operate their own pieces of equipment. They do this
with gusto, and also repair and modify their own
equipment. This is a privilege well worth the effort
to gain, and one to be jealously guarded.

The excitement that drives a Radio Ham starts with
relatively simple technologies at first, perhaps making
his own Wimshurst machine and primary cells. Small pieces
of test equipment follow, possibly multimeters and signal
generators. Then comes receivers and transmitters. It is with
the latter that communication with like-minded technically
motivated people takes off. The scope for technical
development grows with the years
and now encompasses DSP and DDS. There is also a great deal
of excitement in the areas of computer programming to
be learnt and applied.

The technical excitement motivates Radio Hams to compete
with each other to determine who has designed and manufactured
the best-quality station. This competitiveness is found in DXing,
competitions and fox-hunts.

-----OOOOO----

However, beware! A Ham Radio licence is such a
desirable thing to have that there are large
numbers of people who wish to be thought of
as Radio Hams when, in fact, they are nothing
of the kind! Usually such people are a
variation of the CB Radio hobbyist; they buy their
radios off the shelf and send them back to be
repaired; they are not interested in technical discussion
and sneer at those who are; they have no idea how
their radios work inside and have no wish to find out;
they are free with rather silly personal insults.

These CB types engage in the competitive activities
with their Cheque-Book-purchased off-the-shelf radios
in a forlorn effort to prove that they are Radio Hams.

No _REAL_ Radio Hams are deceived by such people!

-----ooooo-----

One infallible way to disambiguate the CB Radio Hobbyist
from the _REAL_ Radio Ham is to solicit their view of the
difference between CB Radio and Ham Radio. A Radio Ham will
perceive Ham Radio to be a technical pursuit and will
perceive CB Radio to be a social communications facility
no different in essence to a land-line telephone or a
GSM mobile in the hands of a 6-year-old. Thus a Radio Ham
could also hold a CB licence safe in the knowledge that
such a licence says no more about him than having a land-line

telephone, whilst continuing to regard Ham Radio as a separate technical pursuit.

A CB Radio hobbyist, on the other hand, sees no difference between a Ham Radio licence and a CB Radio licence. To him, they are sisters-under-the-skin. Wrongly, the CB Radio Hobbyist then tries to classify himself as the equal of the Radio Ham when, in fact, he is nothing of the kind.

Ham Radio is not CB Radio and has no common ground with it! Ham Radio is _THE_ technical pursuit for gentlemen; CB Radio is the operating hobby for those who buy their rigs and equipment off the shelf.

-----ooooo-----

If you are the sort of person who is motivated by a technical interest in how things work; if you took apart malfunctioning clocks, toasters and the like and put them right despite never having seen them working, then a Ham Radio licence is your traditional route! There has never been a shortage of such people, and those who gravitate towards such an interest have always been welcomed into our shacks and their interests fostered. There is not today, nor has there ever been, a need to go out and encourage and press children, children who have never expressed an interest in Ham Radio, to come into our shacks. Such an activity should cause eyebrows to be raised - what normal well-adjusted adults seek the social acquaintance of children?!

-----ooooo-----

Please remember that this FAQ is a _POSITIVE EXHORTATION_ to you to exert yourselves to join our fraternity! (If you find otherwise, then perhaps you are already classing yourself in the mediocre groups of those who are criticised in the FAQ and from whom we _MUST_ dissociate? If so - it's never too late for a re-taxonomisation on your part - there's nothing elitist about us, and we welcome all those who are prepared to put themselves out in order to join our ranks!)

Long ago my Elmer told me a story of a local ham who got the bright (pun intended) idea of putting a large neon bulb at the top of his vertical antenna. Not long afterward, his neighbor knocked on the door complaining of TVI. "How do you know it's me that's causing the interference?" the ham asked. "Because," said the neighbor, "every time that light on the top of the antenna blinks, my TV goes crazy."

The next night the ham was seen in the back yard with a BB gun shooting out the neon bulb.

Your definition of ham radio describes probably less than 20% of
currently operating hams. Social communication is the heart of ham
radio. Maybe technical saavy is the soul. (Newsgroups would
necessarily be the colon... and I don't mean ":")

NO, it's not elitist AT ALL to "disambiguate" (is that a word?) between
REAL hams and the rest of the freaks and losers that "pose" as hams.

What bullshit.

It's a very big tent and there's room for all.

Andy writes:
Reminds me of the time in college when I worked at WRAL in Raleigh,.
They had four big towers spread out over a quarter mile, and I had
to record the base currents at the towers every nite. Pain in the ass.
The chief engr put up a fluorescent bulb at each tower base and I had
to touch each one when I went there. The field would sustain the light,

and the CE could see the four lights each morning when he came in
before power changed , and he KNEW I had been there...
Well, I put about 3 feet of #32 on each lamp, and when power changed
at nite the lamps would glow by themselves... I didn't have to make the

walk and could "estimate" the currents by the line currents in the
station....... It worked fine until one night it snowed. The CE saw
the
lights glowing the next morning, but didn't see any footprints across
the field...... You'd think a bright young college student would
have better sense.... :>))))))

3246. Tube failure mode: gassy?

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-06-17 02:55:10 UTC
From: shoppa@trailing-edge.com
Message-ID: <1150512910.810581.47510@c74g2000cwc.googlegroups.com>
Source record: 11697

OK, I'm trying to understand the failure of a 807 beam tetrode in a homebrew push-pull audio amp.

Tubes are GE, about 45 years old, bought as new old stock several weeks ago.

Being run with 400V on the plate and 255V on the screens.

Both behaved very nicely for a few weeks in my amp, and plate current at idle followed the curves in the books just fine. They were well-balanced.

But tonight under some listening stress the B+ fuse blew.

Turning the bias (supplied from a bias supply through a 100K resistor) down to -40V, the good tube is drawing a small amount of plate current while the other draws 40mA after warmup and current goes up and up and up until it hits 100mA or so and I turn the amp off before blowing another fuse. Check the grid current and as the bad tube warms up grid current is increasing and increasing as well, to the point where the -40V is being entirely dropped in the 100K resistor (I guess that means about half a mA of grid current).

The tube with high current always had some violet-blue spots that danced on the top but they were on the glass and mica so I figured that was normal but now I don't know. There was also this strange orange spot that was on a mica insulator there too.

Is this classic "gassy" tube failure? Towards the end it seemed to be slightly more blueish on the top.

I've burnt up/blown up a lot of 6146 and other variant beam tetrodes over the years but now I'm trying to get some understanding of what's happening :-).

Will a certain chunk of NOS 807's simply be this way from age?

Tim.

You are very kind. However, I shan't stay long
(Cue chorus from the very Childish Broadcasters (CBers)
criticised in the article) becaue I never intended to call
in yesterday.

I'd not even read this group since 17th? March? April?
let alone contributed to it and have been engaged on
other projects, primarily preparing my first anthology
of poetry for publication. I had some time on my hands yesterday,
had a quick look, and there on the front page of Google was a
gratuitous unpleasant remark directed at me from the same
nasty, sick-minded pervert who has caused me and my
family (and, indeed his w*nkmason buddies in the ploddery)
so much trauma over the last 4 years. Why that should be the case
after an absence by me of many months by me, I do not know, but
it shows conclusively that the campaign of harassment
originated with him, and him alone, and continues to be
motivated by his infantile attention-seeking bile.

As before, I have responded only to defend myself, and have done
so by quoting his own nasty remarks back to him.

Anyway having been provoked by his gratuitous and infantile outburst,
I presumed that no-one else had published the FAQ recently and that
it would be overdue for republication. We must all remember that
Ham Radio is a technical pursuit, and one for which sufficiently
interested and motivated 14-year-olds trained themselves. There never
has been any need to lower the standards, firstly by the Novice
Licence, and latterly by the Fools' Licence. If otherwise-unqualified
14-year-olds can do it, then so can anybody.

Grown-ups who are either too lazy or too stupid, or both, to be able
to tackle and then pass the exams that a 6-year old can pass
after only two days' tuition are a joke. Grown-ups who beam
and preen themselves once having passed the 6-year-olds'
are the absolute laughing stock and we should not
associate with them in any way. They are not Radio
Hams by any stretch of the imagination.

John,

My comments are below your text snippets:

> I have for the time being disonnected the first mixer, and am able to feed
> in a 45MHz signal straight into the firts IF amp if I wish.>
> Now if I look at the output of the second IF with a spectrum analyser,
> with
> the power off to the first IF, but with the 2nd LO running, I can wind up
> the second IF's gain, and the noise floor goes up, which I guess is
> expected, but there are no peaks at 455KHz.

This would be expected, as there is nothing to bandlimit the output of the high-gain 455 KHz IF, so you're seeing its broadband input noise amplified by its gain.
>
> If I connect the power to the first IF, and then wind the gain of the
> second IF up, I get a noisy peak at 455KHz, that varies in aplitude with
> the gain. The input to the first IF has a dummy load.

This is also to be expected, as the input noise of the first IF is amplified by its gain, then bandlimited before amplifying in the second IF.

>
> The second LO is a crystal oscillator, see my previous questions regarding
> this.
>
> The question is, should I expect to see a peak, I dont think so.
> What could be causing this? The first IF is in a double sided PCB
> enclosure.
>
> I hope someone can help as this is driving me nuts....

Don't go nuts - it sounds normal. It would be a lot easier to say if everything truly is normal if you could supply some numeric data - fortunately you have a signal generator and a spectrum analyzer. I suggest that you put a signal into the first mixer and observe the output of the last IF on your spectrum analyzer. What input signal level does it take to get 10 dB output signal-to-noise ratio. What level does it take to get the same result feeding a signal into the first IF chain, then the second IF chain, etc ??. Don't worry so much about gain during these tests, just the signal-to-noise ratios. BTW, make sure the analyzer's resolution bandwidth is approximately the same as the receiver's IF bandwidth for these tests, otherwise you'll have to apply a noise bandwidth correction).

Good luck

Joe

Dark metallic. Not whitish, not even on the edges.

Just warmed it up again, and looked for interelement shorts. No shorts, just lots of grid and plate current when negative grid bias and B+ is applied, it seems to "run away" in fact (after 5-10 seconds of bias/B+ the currents start taking off steeply). No oscillations/parasitics on the scope.

I actually have another GE 807 that's been in my junk box for many years (presumed "junk"), and it has a similar getter and similar excess currents (actually worse).

One thing I want to eliminate as a possibility is that something in my homebrew amp did this tube in after just a few dozen hours of service: 390V on the plate, 255V regulated on the screen, about -23V on the grid to give 38mA idle current, all following the classical AB1 parameters in the 40's vintage tube manuals. This is MUCH relaxed compared to typical ham transmitter usage I've done with 807/6L6GC/6146's in the past (which is 700 to 750V B+, 80 or 90mA plate, class C so substantial grid current, etc.) but that was ICAS.

Tim.

If it's 'friend' hasn't expired I can't really see how your amp can be at fault.

Graham

swap the tubes around and see if the problem moves with the tube or
stays in the socket. But I bet it's the tube. The getter only
absorbs oxygen. However other gasses can be outgassed from the
metals in the tube and cause problems perhaps.

You should also check to see if the coupling cap from the driving stage
is leaky.

semi-dumb question: where are you measuring the bias voltage? (directly
at the tube, or on the other side of the grid resistor?)

I'm wondering if a bad coupling cap is causing the bias at the tube to
drift towards 0v or even positive.

Well, I WANT the bias to be circa -20V or -25V. There's a negative supply and some pots which form a stiff voltage divider and supplies grid bias through a 100K resistor.

On the "bad" tube grid current is so high that it does indeed drift up to 0V in a minute or so. Yeah, I know, there's not supposed to be grid current until the grid goes positive. I suspect this is the root of the problem.

The coupling capacitors are indeed good and moving the tube around it follows the tube.

Tim.

I have very little direct tube experience, but from what I've read it
sounds like the grid is emitting. Apparently this happens when some of

the oxide coating from the cathode gets onto the grid, which gets hot and emits electrons, which tends to pull the grid more positive. The current flow on the grid heats it up more, which makes things worse, and it runs away.

In all the old tube books this is a result of mistreating the tube -- running so much cathode current that the oxide vaporizes a bit and condenses on the grid (although it may also happen from positive ion bombardment -- hmm). But who knows what 50 years of sitting in a drawer (or getting carted around) will do?

'Regular' grid current happens when the grid goes positive and collects electrons, tending to pull the grid more negative -- this is why you can self-bias a class C amplifier or oscillator with a resistor to ground.

I have no idea of how to actually test this theory, or what other mechanisms would cause this problem. The best I can do is mention that while 807's are normally $18 at Antique Radio Supply they're on sale right now at $10, and 1625's are still a better buy at $5.50.

Tim,

I think you are on to something here. I ran across this effect with an
old WWII pulse tetrode, the 4D32. The ones showing this effect also had
little white spec's on the inside of the glass that could be "disturbed" by
tapping on the glass envelope. This was in a ham transmitter, and was worse
with rising frequency. At first the runaway occurred on 10 meters (29 Mhz),
and over time it would occur on 80 meters (3.9 Mhz). One thing that always
helped was to reduce the filament voltage from say 6.8 volts down to about
5.5 volts. Many old amplifiers / transmitters run the filaments pretty hot
with today's line voltages.

Might consider late manufactured 6BG6's for $6.00 each:
http://www.vacuumtubes.com/6BG6.html

These are very similar to the 807, and if the claims are true, then these are better.

Jim

This is certainly consistent with what I'm thinking.

> (or getting carted around) will do?

At the same time Allison says that this is what gassy tubes do, too
:-).

The explanation from Allison that there was a small crack at a pin seal
is a bit more easy to use in terms of timing of my particular problem.

> I have no idea of how to actually test this theory, or what other
> mechanisms would cause this problem. The best I can do is mention that
> while 807's are normally $18 at Antique Radio Supply they're on sale
> right now at $10

That's where mine came from, and what inspired my question "are a
certain chunk of 45-year old 807's this way?".

> and 1625's are still a better buy at $5.50.

In fact I have plenty of 1625's too :-).

Tim.

3275. mc3362 and xtal filter termination

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-06-18 12:29:20 UTC

Hi All
I'm trying to use TQF9-02 (similar to xf9b)(impedance 500ohm) filter in
receiver on MC3362.
In original project there was homebrew filter connected to pins 17,19
MC3362 via capacitors 220pf.

Have you any ideas for proper termination of Xfilter?

MAc

3276. A Complex Metaphysical Conundrum...

Hi all,
I once believed that UHF(and beyond) RF electronics was the most
technically challenging hobby there is. Period.
However, I've since read about some chap who claims his principal
'hobby' is Quantum Mechanics! This fellow is in prison somewhere in the
UK and all his 'work' is *entirely* theoretical (obviously - given the
confined circumstances) and consists of the academic pursuit of the
subject alone including heaps of serious number-crunching and
formidably cryptic calculus.
The complex, metaphysical conundrum that arises from this is: can QM
(highly theoretical even if you actually work hands-on with particle
accelerators) ever be accurately described as a 'hobby?'
What does the Panel think?
p.

Andy writes:

If the specified filter termination impedance is 500 ohms, you have
to take the 3362 input impedance and transform it to 500 ohms.
I don't know the 3362 input Z, and am too lazy to look it up, but most
likely it is higher than 500 ohms and has a capacitive component...
So, use math to find out what the parallel R and C is, and things
will start to make sense...

Lots of ways to do this, but ALWAYS use a tuned circuit. Otherwise
you will have a reactive component that will mess you up...

Personally, I like to use an inductor and two capacitors, since it
provides DC blocking. Some people like transformers......

Andy in Eureka, Texas

PS Rp = Rs (1 + Qsquared)\

Xp = Xs (1 + Qsquared) / (Qsquared)

Q = Rp / Xp or Q = Xs / Rs

If you put these in a Basic program, and learn to use them, it
makes things a lot quicker....

Quantum mechanics is a science - you don't *prove* anything. You make theories to explain data obtained by experiment, and verify the predictions of these theories with more experiments. Anyone looking for a subject whose results can be proven should stick to maths (another good choice for people stuck in prison!). But as a science, QM is solid (if somewhat difficult) - just because the guy in prison can't personally verify any predictions he comes up with, doesn't mean they can't be verified by others. After all, much of the theory is developed by people at universities, not just the more "practical" scientists working with particle accelerators and the like.

I have used tubes with the "gassy problem. I got the tubes free because
of the problem.
I used the tubes in my transmitter by biasing the tube with a very
stiff bias supply. I used
a choke coil to get the bias to the grid. They were 829 tubes and were
used on two meters.

> slightly more blueish on the top.

The violet - orange colouring only ever occurs as a tube dies from gas
intake. Normally
the tubes should have a slight "royal blue" low level flurescence usually
visible in darkness.
the bright blue flickering is the end for the tube; its only good for the
bin unless you
salvage the tube base plug for a multi wire plug.

After turn on with the output tubes in you should measure the voltage
across each bias resistor
from supply to grid pin. Usually the gassy tube draws grid current at idle

with the grid becoming
positive with respect to the bias supply.

Just what has caused the gasiness in anyone's guess but to test the
coupling caps remove the
output tubes and measure dc voltage across the biasing resistors to the
output tubes.
There should be less than a mV after leaving the amp on for an hour.
Using 807 from WW2 NOS could be dodgy since gas leaks could occur; not
enough to turn the getters white
or even slightly brown edged but enough to cause rapid failure well before
the usual 5,000 hrs you should get from a hi-fi output tube.
But then I have just repaired an ARC VT100 and out of 8 brand new Ei 6DJ8
there were two
which were quite faulty because one of the twin triodes in each tube became
gradually saturated
and fully turned on for no reason other than they had been poorly
manufactured in Yugoslavia.
Nice gold lettering on the outside, crummy work inside.

>
> I've burnt up/blown up a lot of 6146 and other variant beam tetrodes
> over the years but now I'm trying to get some understanding of what's

>
> Will a certain chunk of NOS 807's simply be this way from age?

Youse takes your chances with ancient 807.
They usually were renowned for their ruggedness but heck, anything ancient
must surely be less reliable than had it been made yesterday to the same
spec.

Would you fly in a NOS Mustang P51 that was NOS?

Not me, that's fo sure.

Maybe I got 20 x 807, I dunno their history, and I ain't got around to
using any; maybe I never will....

3291. is an STA needed to transmit data on CB channel 40?

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-06-18 17:41:25 UTC
From: eternalsquire@comcast.net
Message-ID: <1150652485.685726.246160@c74g2000cwc.googlegroups.com>
Source record: 11742

All,

I've got a brother who works for a consulting firm whose main customer is Homeland Secrity.

What the feds want to do is to be able to communicate mil-spec digital packets over low power links in the middle of a disaster-hit area between squads of Guards deployed across a destroyed city.

They cannot assume that hams and ham equipment will be available, and they do not want to carry heavy equipment into a city. They want to be able to use equipment that they can readily commandeer from stores such as Radio Shack.

That pretty much means CB radios. I have heard of hams working DX using 5 watts of PSK on 10 meters using poor antennas, so that gives me the idea that Guard units could form medium range mobile networks using 5 watts of PSK on 11 meters using wires dropped off bridges.

Eventually the hams that do get on the scene could set up a CB to HF gateway so that the packets could make it out from the Guards to the NGOs.

While I am more than willing to test this setup out for my brother on a pair of CB radios, I told him I might need an STA from the FCC to communicate data on CB channel 40. He tells me that in an emergency, anyone can use any frequencies they want, any power, any mode. I told him true, but that does not help me as an OEM getting fined for testing out an emergency scenario in a nonemergency situation.

Suggestions?

The Eternal Squire

It is a hobby if you're a physics Ph.D. who can't get an academic job :)

There are people who do astronomical computing (calculation of orbits, etc.)
as a hobby. I suppose this is similar.

As a not so bright college student, I can safely say that even the smartest people can fail to have common sense.

Case and point. I worked for a small tribe in Cordova Alaska installing communications for a sonar fish counter camp about 27 miles outside of town. While this location was on the road it was in the middle of the cooper river delta and should be considered quite remote for the purposes of this story. One of the smartest people i've ever met was responsible for specifying the sonar and doing most of the hard science behind the counter. He was happily standing on the bridge overlooking the river probably pondering some complex function of acoustics and leaned over and watched his keys tumble into the river.

Animals tend to have a bit more common sense than highly educated people; while people who live outside the norm know to keep the keys in the ignition in a situation like that.

Funny how life works out,

The CB band is close enough to the 10m amateur band ,such that when the test
is done within the amateur band it would also be valid for the CB band .
Although you might have to do the test in the 10m amateur band with 300 baud ,whereas in the CB band you could use 1200 Baud.
Unless the 300 Baud limit in amateur allocated HF bands has been / can be lifted.

Well, I know that some people persue mathematics as a "hobby". Nothing
could be less hands-on, but it's a hobby nonetheless.

I can't believe they would be asking a company with such a lack of knowledge
that you have to post a message to a newsgroup!
I think you're telling a bit of a fairy tale. They wouldn't be using CB as
there is a vast array of communications equipment already in use - or did
your brother forget to tell you that.
What's the name of his company so we can all avoid what appears to be bunch
of amateurs.

E.S.-

With all due respect to your brother, this is an extremely unlikely
scenario. While a common AM CB radio might be modified to perform the
task, you aren't going to commandeer one from Radio Shack that a Guardsman
can adapt for such data transmission.

Just how heavy do you think a data radio would be? A unit as small as the
smallest CB could be designed to perform the function (and may be
off-the-shelf). In other words, such a data system MUST be carried in to
ensure it is going to work, and it won't be so "heavy" that each unit
can't have spares handy.

jawod <jawod@fuse.net> wrote:
>It's a very big tent and there's room for all.

Actually, it's a very small tent and there is NOT room for all:

Let's crunch some numbers: Our total MF/HF spectrum consists of just 3.75 MHz, with only about half of it, 1875 kHz, useful for communications at any one particular time of the day.

With that in mind, let's look at some worst-case scenarios: If suddenly, as if by magic, all licensees were granted MF/HF privileges, we could possibly have 670,000 hams attempting to fill that 1.875 MHz. Okay, I'll grant you that folks have to work and sleep, so let's say at any one time, we have one-fourth of all 670 kilohams on the air, with two per QSO. That would mean each QSO would be separated by just 22 Hz.

I'll be more generous. Let's pretend that all 3.75 MHz is available all the time, with say, one-tenth of all operators on at any one time; now each two-person QSO is separated by 112 Hz. Getting better.

Worried that I didn't take into account frequency re-use? Alright, suppose we could manage three simultaneous QSOs spread across the country on a single frequency; each such grouping would now be separated by 336 Hz. That could be done if we ban phone.

I'll never understand this liberal mentality of wanting to grant everyone MF/HF privileges; it's no longer a privilege if it's something that everyone can get practically for free. We recevied our current spectrum total at a time (WARC 1979) when we had less than half the present number of hams. That shows that this movement of wanting to "fill up the bands or we'll lose them" is pure nonsense.

As Michael Savage says, "Liberalism is a mental disorder."

I think you're correct. Part 95, section 631 (c) and (e) and (f)
make it quite clear that data transmission over CB is a no-no.

In addition, the simple act of hooking up a data transmission circuit
to a CB radio's modulator might be considered to be enough of a
modification to void the transmitter's certification.

Applying for an STA certainly seems to be the safe thing to do. And,
if you get one yourself, the end-user agency should probably also get
one, so they can run periodic tests and drills without breaking the
rules.

>The Eternal Squire

I for one think this is a bit hairbrained. But here goes...

Actually you can break the task down two several larger problems.

Is AM modulation suitable?

What connectors? The average CB uses one of ten different mic
connectors and of those the same type none are wired the same!

Forget internal mods, they are very different from unit and
some are surface mount construction. Also type acceptance
and operating rules) prohibit most data, image and modifications.

How will they power the CB radio? A 5W radio under full TX
modulation want about 15-20W of power (1.5-2A) SSB versions are
far more power hungry (2-4A on TX for legal radios and the import
illegals can run far higher.).

Radios vary widely from real junk to near decent so you need to find
examples of the worst to be sure your not encouraging an interference
generator.

At this time RS is closing stores and I think at most they carry only
a few (if any instock) different CB sets. You'd have better luck at a
truck stop!

What do thy expect to use for an antenna? The average CB set will
fry the finals if the antenna isn't tuned reasonably well.

You can test the basics using dummy loads before you get into
the STA.

FYI: GMRS radios present a better choice and are more widely sold.
GMRS being higher power thn FRS and often better radios for short
range (UHF FM) ops.

I have seen it with many NOS power tubes in this power class. Doesn't
seem to be a problem with bright filament types but maybe it can be.
Fix is to throw out the offending tube.

If you can't get NOS tubes at Surplus hut prices, my advice is to buy
NEW tubes. From someone you can get a refund from.

I think this is a misreading of the rules.

Yes, if someone's ship is sinking, or someone is lost in the mountains,
it is far better to use what's available than die. But, I seem to
recall some cases in the US where someone just blasted away, and it
was deemed later that the emergency was not serious enough.

But, the scenario you are talking about is not the same thing. You
aren't talking about someone trying anything to save themselves, you
are talking about organized emergency work. And once that starts happening,
you can't have anything goes, for the same reasons that there are
rules to regulate radio under non-emergency conditions.

If you blast away at any frequency or any power, then you could
so easily interfere with some other legitimate emergency communication.
Your communication may not be more important than someone else's, and
hence frequency coordination is just as important.

It has been long argued that one reason to keep amateur radio around
is that in the case of a big emergency, it's relatively easy to put
amateur radio to rest, and then you get some big chunks of spectrum
that won't be used for necessary or emergency communication. IN other
words, using amateur radio frequencies is one scenario that is already
planned if the emergency is important enough (aside from it being
used as auxiliary communication with hams using their existing
equipment.

But, life goes on, and you can't superimpose a lot of communication
onto frequencies that are needed for existing communication needs
which won't go away when an emergency comes along.

And on a completely other note, as others have pointed out, even
if an existing communication band is the only choice, there are far
better choices than the 27MHz band. A big problem of that band
is that when the skip is in, it's made fairly useless because
distant stations come in nice and strong. And likewise, you
want a band that's good for local communication, and the fact
that you can get great range under good conditions on 10meters
is not the same as getting good reliable local communication.

Very well said.

The mantra that we must "attract new blood" has been shown, in
Britland at least, as a piece of propaganda to help fill the coffers
of our national CB society - the RSCB.

There has never been a shortage of _REAL_ Radio Hams.

Wow, looks like consultants are the same the world over - come up with lunatic schemes, and get paid lots of money for them.

Tell him to get a real job - it will pay less, but he wont be held responsible after the next major stuff up.

And tell him to buy a text book on - well, just about anything except self-promotion - he doesnt seem to know very much. Probably why hes a consultant. Is he an accountant?

And dont the National Guard units already have radios - they have been issued to military units since, lets say, 1918 or therabouts.....

What a wonderful scenario - due to basic functional stupidity, the disaster plan is contingent on being able to commandeer radios from stores, and , with a swiss army knife, modify them for data communications. There is, of course, a team of trained technicians with the advancing relief workers who can do this.The data comms gear is already with the people trying to get it to work on the commandeered radios.......

Get real people - this is either a post from someone taking the mickey out of you guys, or, if it is a real, serous idea - make sure you dont need any external help if a disaster does happen in your area..... sounds like organising a frozen chicken raffle would be straining their ability..

Andrew VK3BFA.

I suggest that you consider using the unlicensed MURS band for this.
Unfortunately you cannot just walk in to a walmart or radioshack and
grab a MURS radio. Rather visit rkleef.com and look at the MURS22
units, or google for the "dakota alert" MURS radios.

Good luck,
--John

IMHO The feds have plenty of radio equipment with comms operators that could
be shipped to disaster hit area faster than your average guards unit could
adapt/setup a purloined unit.

Thank you all for your suggestions.

This is not a hoax. But I too find the need sufficiently implausible
that I feel a little bit queasy taking R&D fees for a cause like this

at $50 per hour. The only reason that I'm not mentioning the consulting firm is that I could stand to get paid... and any money is better than no money. And if I'm the king's coin then I ought to make it work.

I agree, Truck stops are a very good idea for commandeering CB's, but you only find those in the exurbs.. Yes, other commercial radio services could and maybe even should be drafted into this. The squad lead could then determine the tradeoffs based on the availability of foraged equipment.

Allison, your idea of using the dummy loads to simulate fading over distance is OUTSTANDING. I'll do it!

Using dummy loads as a demo, I could then get the consulting firm to ask the FCC for an STA for field tests.

For my test rigs, I'm intending to plug in a laptop sound card I/O into the SSB mic and headphone jacks. Therefore no type acceptance needed because no mods.

My brother says ideally in the scenario, each squad leader should only need to carry a mini-CDROM in his or her pocket. The squad lead could then commandeer a laptop, an SSB CB radio, and then use an abandoned automobile as an electric generator for the laptop and radio. Antenna would be flung over a 3 story office building.

One of the reasons for this scenario is to lighten the overall squad load and thereby increase the speed of response. That way each squad could break into an abandoned store and then set up a first responder posts.

Let's see, all you have to do is find a bunch of laptops with 12V
adapters, a bunch of CB radios with documentation on the mic input,
a soldering iron to make up a mic/laptop interface cable (assuming
you can use the existing mic cable connector).

The only problem left is how to get the abandoned automobile to the
top of the 3 story office building (if any are left standing in this
disaster).

You know, sometimes as a consultant you just have to find a way to
tell the customer he is crazy but you have an altenate idea that
they might like in acceptable language.

Seems to me it would be easier to come up with a plan to stockpile
and distribute standard squad radios the troops already know how to use.

But I'm just a retired Army signal guy, so what would I know?

The CB band is also listed under the license free regulations, Part 15
so if you run low enough power, you don't need a license, and there are
no particular restrictions on mode.

> 15.227 Operation within the band 26.96-27.28 MHz.

Channel 40 is above 27.28 MHz, about channel 27 as near as I can tell
(channels are not sequential frequencies).

Contrary to popular opinion, I think that a packet radio relay made with
a portable computer with a sound card, a CB transceiver, and a patch cable
all made from stuff that you could "liberate" from the local Radio Shack
is possible. Some sort of PTT control (VOX?) would be the hardest part.

Given my opinion of the average CBer's conception of "The Public Good",
I don't expect that a system could run without getting the hell jammed
out of it, even if the military is exempt from FCC regs.

First of all: The Federal Government (ie Homeland Security, USCG, US
Army, ectg) doesn't need, or require anything from the FCC, as the FCC
has no jurasdiction over US Federal Government Radio Operatrions. It only
regulates, non-Federal Government Communications. The Office of
Telecommunications Policy, or whatever they changed the name to recently,
is the Clearing House for ALL Federal Communications Operations.

Second of all: Even if you did apply for an STA, the FCC wouldn't grant
it for 27Mhz, as that would specifically go against a Standing FCC
Regulation, and set a very bad policy statement for the future.

Last of all: AM Modulation is the worst type for trying to get error
free communications, and not likely to succeed without spending a pile
of money in the R & D Phase of the modem part of the project.

Me an ex-FCC Field Resident Agent who knows better than
to go down this kind of path.....

The US ARMY radio & TV station I worked at had FCC licenses hanging
on the walls at Ft. Greely, back in the early '70s but they were
considered "Courtesy Licenses" so the FCC knew to keep track of them
when other stations were built. They had no expiration dates, now power
limits, and no operating hours. They were marked "Until no longer
needed", and "As deemed necessary" and at that time were issued to any
long term US Government RF installation.

SSB CB radios are pretty rare items in most circles, in fact the troops trying to commandeer CB's might not be aware of the difference and will try to use standard CB's and they won't work in the "net". Secondly, SSB CB's have a clarifier control that has to be adjusted. This is easy enough with voice, but with data, it is not as easy to do by "ear". You will have to incorporate some sort of tuning scheme in your software. You are better off with AM because of these limitations. Are you going to have a field expedient handbook so that the troops can figure out which mike wires are which? It is not that easy to figure out if you are unfamiliar with radio. Your idea of a software solution reminds me of the BAYCOM TNC modems of the 80's. You might want to research those. You should be able to get 3 to 5 times that rate in the consulting world by the way.

Then I guess if the consulting firm can get the necessary authority to
waive the need for an STA, I won't complain.

> Second of all: Even if you did apply for an STA, the FCC wouldn't grant
> it for 27Mhz,

If the FCC was trying to prove itself modern for digital commo by
trying to kill amateur HF using BPL, then with this they have a chance
to let CB'ers enter the digital age. Maybe the FCC will go for it..

Funny, the last laptop I bought doesn't include a 12V cable. As a
matter of fact, neither did the one before it. You had to ask for
it as an add-on.

> a bunch of CB radios with documentation on the mic input,

> The docs could be on the CD-ROM. Squad leader or designate
> could read that using the laptop.

And just where do you get this CD-ROM in a deserted, destroyed building
after the catastrophe?

Oh yeah, you've got the schematics of every CB radio ever made on
CD-ROM already and you are taking it with you.

Right,

> > a soldering iron to make up a mic/laptop interface cable (assuming
> > you can use the existing mic cable connector).
> Shouldn't be too hard.

Of course every squad made up of random troops from the motor pool and
the rifle squad has a portable soldering iron, knows how to solder
and has solder.

Or or all these troops going to come from the Signal School?

Oh, wait, they are going to commandeer the soldering irons and solder
from the destroyed businesses and plug the irons into the none-functioning
AC grid, and learn how to solder from a CD-ROM.

How could I have been so stupid with only 30 years in the Army?

Maybe from teaching soldering classes?

So where do you get the custom power cable or antenna cable to go
up three stories?

Three stories worth of cable is going to weigh a lot more than most
radios these days.

Might as well bring the radios with built in antennas and battry packs.

Clearly you are only skimming my posts rather than reading them.

Starting at the beginning:

1) Squad leader carries a mini-CDROM in his/her pocket. That's the
nucleus
for everything else. With luck, nothing else need be carried into
the field.

2) The CDROM would contain schematics and part numbers of everything
necessary
to forage to create a datalink.

3) SSB CB Radios (funny, my RS always carries the SSB CB radio as the
high end
model) would be one of several pieces of RF equipment
that could be foraged off the street (i.e. Radio Shack stores,
truck stops, etc).

4) Most new laptops carry 12V power input. Older ones don't. There
are plenty
of sources to forage a laptop from: Target, Walmart, and K-mart
come to mind
as well as Radio Shack.

5) The laptop, radio, and car are all at street level. People can
take plain old copper
wire and make a dipole or inverted Vee with it, hanging it from the
roof top. The only actual ground to antenna connnection comes
between the radio and the center of the dipole or inverted Vee.

Caught up now?

Thats funny! Actually CB radios are very diverse with their mic
wiring and switching schemes as in if not done correctly they will
not transmit _or_ recieve.

It's a bad idea and deserves to die an expedient death.

It would be far easier to mass produce a UHF FM radio based on
GMRS chipsets with a digital interface. Then give everyone
a box of them and a box of batteries.

I bet that's it. I'm in WAAA-shington and it is incredible how
absolutely clueless the folks who staff the consulting firms are.

They'll seize upon a buzzword or a weird concept and, bing, the word
processors and powerpoint presentations are running full time,
filling the air with blather.

Handwaving, spewing the jive.

Let's be clear. The concept makes no sense at all. Others have
detailed the technical and practical issues.

What does work is standard military comm gear, ruggedized, charged
up and ready to use.

This is America. The guard or whoever already has comm gear, likely
as good as stuff used by 14 year old mall-kids.

If they don't, then it's a simple matter to deliver it to them from
a depot.

In the absense of a problem, a consulting firm will imagineer one
and, let the spew-games begin.

This is WAAA-shington. Blather and cluelessness abound.
They might be filing for a proof-of-concept, stage one,
small-business-innovative-research contract, twenty-five or fifty
grand of your money pays for a lot of USENET trollin' and wacky
verbage.

Even scarier, if they make the first cut, the next level is a
quarter million to a half million dollars of YOUR money.

STA are temproary and not supposed to be granted for perment possible
ops the people ask in this case would the FCC iself but I an STA would
allow protype testing and such but deployment authoity would need some
mondo rulling to be legal

Actually, I was reading them and comparing them against my real world
experiences with combat boots in the dirt.

> Starting at the beginning:

> 1) Squad leader carries a mini-CDROM in his/her pocket. That's the
> nucleus
> for everything else. With luck, nothing else need be carried into
> the field.A

A military force that goes into the field depending on luck is doomed
to failure.

It doesn't matter if it is a combat situation in foreign land or a
simple training exercise within sight of a major US city.

If you don't have everything you need going in, or at least a supply
chain that can get it to you quickly, someone is going to be hurt.

This comes from bitter experience.

> 2) The CDROM would contain schematics and part numbers of everything
> necessary
> to forage to create a datalink.

You are going to supply an up to date CDROM containing all the info for
all the CB radios in the US?

Yeah, that's going to happen

> 3) SSB CB Radios (funny, my RS always carries the SSB CB radio as the
> high end
> model) would be one of several pieces of RF equipment
> that could be foraged off the street (i.e. Radio Shack stores,
> truck stops, etc).

Assuming there were such stores in the first place and they aren't
flattened/flooded by whatever the catastrophe was.

> 4) Most new laptops carry 12V power input. Older ones don't. There
> are plenty
> of sources to forage a laptop from: Target, Walmart, and K-mart
> come to mind
> as well as Radio Shack.

Getting a laptop is a minor problem. Getting a 12V DC connector and
someone that knows how to wire to a field expediate power source
correctly is a major problem.

> 5) The laptop, radio, and car are all at street level. People can
> take plain old copper
> wire and make a dipole or inverted Vee with it, hanging it from the
> roof top. The only actual ground to antenna connnection comes
> between the radio and the center of the dipole or inverted Vee.

Where does the antenna feed cable come from? The collapsed/flooded
store?

Where do you get the person that knows how to wire up an antenna
and feed cable?

Where do you get the person that knows how to cut a dipole or
inverted-vee, or even what those terms mean?

Most troops are really good at what they are trained for. Few troops
have been trained in anything to do with electronics or even electricty.

Special Forces troops are probably the most veratile of troops (and
the smallest in number), but without the training they would be
useless.

You want them to parachute in during the dark of night, take and
hold a tactical position, no problem.

You want them to cut and connect a diplole, big problem

Upon what do I base these statements?

Years spent teaching such subjects to troops.

> Caught up now?

I never was behind.

You, however, have no concept of what it is like to have boots in
the dirt.

I guess it is the new laptops that use 12v, the only laptops I have here have an 18v adaptor for the Zenith or 120v input for the Toshibas. I guess noone will be borrowing mine to use in an emergency. What sort of emergency responders are going to be sent in with no equipment?

With the right soundcard software a laptop could emulate a bell 202 or 103 modem over AM radio, even with packet error checking to reduce transmission errors. What no one has mentioned yet is channel usage, one simplex data channel for an entire disaster area with no provision for collision detection between users other than just listening for someone else transmitting? With the central data collection point high enough to cover the entire area, you will be in the position that each transmitter may not hear another but the reciever can hear both while transmitting at the same time. The data collector would spend quite a bit of time acting as net control determining which remote site was allowed to transmit at any particular time. Just my $.02 on this poorly thought out idea.
thanks, John.

Seriously, hams have long been responsible for taking time wasting idiotic non feasible "ideas" and VERY occasionally turning them into serious modes of communications.

I agree that in this particular case the original idea has several enormous flaws. But with some of the modifications suggested here I think there may be something of some value in some emergency circumstances.

Certainly the professionals who set up digitally trunked comm systems have a less than stellar track record at actual success (do NOT confuse with "contractual success") and I have a large chip on my shoulder regarding ALL the billions of dollars that they've wasted at taxpayer expense. Not to mention the distortions they've caused to frequency allocations that actually WERE previously useful.

And you would be SERIOUSLY surprised at some of the far stupider flawed ideas that are being funded by government agencies.

Tim.

Hi Tim,
not disagreing with you in some aspects - amateurs have had a long record of innovation in the comms field - this scheme, however, is seriously flawed on a basic, technical level. Is there ANYBODY in the emergency management chain who has enough BASIC KNOWLEDGE of communications theory and practice to know that its a stupid idea to start with? - that, to me, is the really worrying part.

There would be FAR more easy and efficient means of getting field comms going - most of them were raised following Hurrican Katrina. Vis

- having common liason frequencies between the various emergency services - they had lots of sophisticated equipment, but couldnt talk to each other beyond sending "runners"

- having backup generators and power available (preferably auto start) on the cell phone and landline systems. And the simple technical ability to lock out non-essential users. This USED to be a basic engineering specification - what happend?
- having someone in charge who could CO-ORDINATE resources - lost in paranoid state/federal/local turf wars.

These are the most basic physical infrastructure issues, , let alone the politics of blame - have they been addressed post Katrina? - the whole world watched in stunned amazement as the Americans couldnt even organise a relief effort for their own people, on their own soil, with no one shooting at them.

And sorry, but when lunatic fringe ideas like "lets commandeer CB's" are even remotely taken seriously out side of a bar room, you have good reason to be worried.

Andrew VK3BFA.

You know, then again the idea doesn't want to know.
If they (the first responders) find a working (unwet and

undamaged) CB radio, battery and antenna they could
just pick up the mic and TALK. That would would be
both cost effective and requires far less effort/training to
implement. It would also conform to the CB norm and other
<gasp> operators might be part of the assistance. There
may still be people working the REACT system.

For those that remember before CB became littered with
carriers and other flotsum and jetsum CB was considered
a very good tactical radio due to it's channelized character.
Since then portable amatuer HTs, FRS and GMRS radios
became available and reliable and share in that tactical
capability without the need for a 9ft whip.

Americans are always planning for war. It's an inbuilt disposition.

That's the best way of guaranteeing they will get it sooner or later.

Witness Vietnam, Iraq, Afganistan, Palestine and many other places.

But keep the Chinese, Russians and Indians in mind. No danger from
them. But they are in a position to retaliate in kind.

Why not plan for Peace! It's safer!

3349. Tradeoffs of filtering exciter vs after PA

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-06-20 18:58:31 UTC
From: Ben Jackson <ben@ben.com>
Message-ID: <slrne9ghan.2vka.ben@saturn.home.ben.com>
Source record: 11550

I'm still working on my HF APRS beacon idea (25MHz-14.85MHz = 10.151)
and I've done some experiments using a 74HC86 quad XOR with one gate for
each oscillator and one as a mixer. In spice simulations, the '86 as a
mixer produces lots of products resulting from the odd harmonics of the
inputs, some of which are close to or below the 10.151MHz I want. If I
run that output through a 2nd order Butterworth 30m bandpass filter I
get a clean result.

My question is about the tradeoffs between filtering the exciter output
to the PA vs filtering after the PA. Obviously a post-amp filter has
to handle more power, but has the opportunity to eliminate amplifier
distortion. But eliminating unwanted inputs to the amp also reduces
unwanted outputs.

Are there rules of thumb for suppression of unwanted signals at each
stage of an amplification chain?

E.S.-

You are not easily discouraged!

Consider that many who have posted negative comments here, have years of experience in the military. Others have experience in providing communications systems for field deployment. Their comments may not have addressed all the points you posted in order to maintain brevity. I detect a consensus that your brother's proposal is not practical, even though it is theoretically possible.

Reading your postings, I can't help but recall two experiences from my youth:

1. A snipe hunt.

2. Trying to catch a bird by putting salt on its tail.

Steve,

I am almost positive that this transistor (PT4370C) was used in the
Transworld RF amplifiers.
There is a Motorola MRF equivalent.
RF Parts will either have the parts or a Motorola cross reference.
http://www.rfparts.com/mototran.html

Look here:
http://www.rfparts.com/pt.html

If you post this question on QRZ Q&A, one of the regulars use to work at TRW
during that era - likely has the old spec sheets and any history you may
want.

Over the years I have read many articles on how to build a linear amplifier. Many of the plans called for glass fire bottles (811, 572, 3-500, etc.). The tubes are always hidden in the back of the amp. Wouldn't it be nice to move them up front behind a piece of high temperature glass and a fine brass screen for shielding purposes. Then we could enjoy the true glow of the tubes.

I am sure that there are a myriad of reasons for not doing this and I am too inexperienced to understand why. Is such a thing possible and if so I might just upgrade my ticket so that I can build such a beauty. I will upgrade anyway just for my own satisfaction.

Think how impressive an amplifier with a tube or two or more glowing behind a picture window would be.

I would appreciate any thoughts on the subject.

Since the filter loss depends on the ratio between the loaded-Q and
the unloaded-Q and in order to get a steep bandpass filter, the losses
are going to be large with ordinary LC components.

If you put the steep bandpass filter after the power amplifier, a
large amount of expensive RF fundamental power is lost in the filter.
However, if you put the steep filter before the power amplifier, the
loss of signal level is easily compensated for by an extra low level
amplification stage, with minimal extra cost.

Depending of the linearity of the power amplifier, some low pass
filtering may be needed after it, but now you have to worry only on
the harmonics of the 10 MHz signal, not the various mixing products.
If you use a push-pull power amplifier, the first significant harmonic
would be the 3rd, which is above 30 MHz and since this is a single
band design, it might even make sense to use an elliptic low pass
filter, with a resonant notch at the 3rd harmonic.

No idea if this is any help at all, but...

I have a TRW data book from 1979. Doesn't list PT4370. Closest number is PT4570. PT4570 was a wierd TO-117 case; stud mount with 4 radial leads out of the transistor capsule. Two E leads opposite each other; C is the one with the pointy end.

This was NPN, 40 V, fT 2GHz, dissipation 5 W.

I have no idea if this is anything similar to the one you want, but though I'd pass the closest I found, just in case it might help.

Andy comments:
I agree with you completely. I suppose that is is a lot more trouble
to put
a glass or plastic window on the front panel, and that the majority of
builders
are looking more to the goal of putting the amp on the air than using
is as
a piece of art.....
Back in high school I built an amp using four 811As and had two 866
mercury vapor rectifiers in the power supply. Beautiful violet glow
would
light up the room and pulse along with my code..... Since I was on a
budget, and had little access to metalworking equip, all of my stuff
was
open chassis with a front panel. I could see the plates of the 811A s
swell
and glow cherry red when I kept the key down for too long.....
Personally, I have no talent for the artistic, so I'm sure any
attempt
I made at "pretty" would be second rate at best.... But I have always
liked to build my own, and take a great deal of pride in my stuff, even
if

it isn't always really "nice" to look at...
I am retired now, but developed dozens of communications products
over
my career. I always tried to work with the best mech engineer I could
so he
could be responsible for the appearance, and the products always seemed
to
end up looking good -- no thanks to me......
I appreciate your attitude, and wish more people would build their
own and
take pride in the appearance. Personally, I think the old rigs --
Viking Valiant,
Hammarlund HQ180, Collins S line --- would be great examples of tech
art,
and should have a place in the Smithsonian.... This new stuff with all
the
lights and readouts and switches and microprocessors just doesn't
convey
the same sense of the hobby to me..... I know how to design and buld
it,
but it just doesn't "feel" the same...

The replies to this aren't showing up on my news server, but from google groups I see that

Doug Smith asked:
> I realize this doesn't really answer your question, but isn't 10.15 the
> band edge - and out of the band once you apply modulation?

With LSB and ~2kHz tones it's actually back *in* the band with modulation. HF packet is FSK, and the mark/space for APRS are at 10.149.200 and .400. When implemented as AFSK + LSB + modem you have to take into account the modem tones, which vary considerably. In fact, you can use USB and tune below the band as well. If you google "hf aprs" you'll find a bunch of tables for various radios and TNCs.

if you do it agter the PA you get those products plus IMD to create
more products and it will be very hard to secure a clean signal
without high losses.

>Are there rules of thumb for suppression of unwanted signals at each
>stage of an amplification chain?

Start clean, then clean up anything that results from the stage(s).
Usually if you have a clean source and run that through multiple
linear stages you should get the same only bigger with only a
small number of artifacts that are easy to clean up.

It's been done.

The ARRL Handbook "One Band Amplifiers" (in my 1962 edition) didn't
use glass, but perf aluminum, but the tubes were still somewhat
visible.

Of course, the Collins KW-1 is a commercial example.

Hey my man, what you may have is a classic case of the grid coupling capacitor breaking down and killing your bias on the grid. It is not uncommon for the grid to go positive and cause the tube to melt!!

And it looks good. If you want to have an excuse, use tubes that are
expected to show some color on the plate when loaded up properly.

I think that for many years the handbook and QST editors strongly encouraged any high voltage parts be hidden away under multiple layers of metal, probably out of concern for safety reasons.

In the 50's and 60's there were multiple articles where the low-power tubes were put on top of the chassis but any tube that had the anode on the top went either under the chassis (often mounted at a very odd angle!) or in its own metal box. It couldn't have been generally good for those tubes to put them horizontally (in fact power tube books often tell you to expect reduced life when tubes are operated in non-vertical orientations) and away from airflow.

For the really big power amps with forced air cooling, noise from the blower is a concern to many hams (hey, we don't spend ALL our time talking!) and sometimes this relegates the tube, air chimney, and blower to the rear as much as possible. I think we've learned a little bit about air cooling and also today have much quieter blowers available off-the-shelf.

For a bandswitching amp, relation of front panel controls/shafts and the tank components/switching often determines the layout of the entire amp. The constraints can be quite compelling if you are trying to cover a decade or more of RF spectrum (say 160M to 10M).

A lot of professional BCB transmitters from the 20's through the 50's put the power tubes (sometimes just the modulator, other times including the RF tubes) up front behind a glass window, just like you want.

Tim.

Ah. Makes sense.

I do direct FSK so have been taking carrier frequencies literally. (and
haven't done datamodes, except CW, on 30 meters so I'm not familiar with
APRS practice on that band)

Tim, good message, but I would disagree a bit with your last paragraph, having spent 1953 to 1956 at Army station ADA in Tokyo. Three-dozen-plus HF beasties there, RF power out from 1 KW to 40 KW, except for one model they were all old ones from pre-WW2 to post-WW2. For more, see:

http://sujan.hallikainen.org/BroadcastHistory

Scroll down the page and click on "Military." My photo essay description is there as My3Years.pdf and is 20 pages, about 10 MB worth.

Of all of them, the old Press Wireless PW-15 had large glass windows for the final amplifier (15 KW CW) compartment and the blue-glowing gas rectifier tubes in the power supply section. When a storm came up the "extra" electricity might cause the final to arc over. That would scare the <something> out of you if you were close to it at the time. :-)

In my opinion, the cosmetics of the front panel would be the most appealing to all. Everyone will see that and not all would be interested in lots of metal working or glowing containers of vacuum. :-)

When I first started traveling Alaska as Traveling Radioman for Northern
Radio Company, I serviced all the old N-529E 2-12 Meg AM Sets that all
the Salmon Canneries used to communicate with the ACS Stations. They
all had 807's, 6146's, and 866A's, that glowed behind perferated screens
in the front panels. Most of the Cannery Radiomen had Ne-2's taped to
the HV Antenna feeds that would glow when the transmitter was online.
Those Radio Shacks were an errie place in the evenings when the last
Radio Scheudal of the day was happening. Orange Neon, Blue Mercury Vapor,
and Dull Red on the Tx Tubes. some of those puppies would crank out 200

Watts Full Carrier Power.

Bruce in alaska the last of the Cannery RadioMen, in alaska.....

Depending on the bandwidth of the filter, typically, the natural impedance
of the filter will be anywhere in the range from 1.5k to 7k. Using ECS
10.7MHz crystal filters as an example, the 50kHz filter has an impedance of
around 6.5k, while the 25kHz filter has an impedance of around 3k.
Most crystal filter don't have a low impedance, but there are exceptions.
The 330 ohm impedance that you describe is typical of the Murata 10.7MHz
ceramic filters. An example would be the SFE10.7V, with a 13kHz bandwidth.
The skirt selectivity on these types of filters is very poor, so about the
only use that they really have is as a roofing filter at the 1st I.F. of a
dual-conversion receiver.

> architecture that minimizes cap current?

I used ceramics in a high power filter and they just fried.
Definately us silver mica, and values up to 3nF shouldn't be a problem.
It's not the power dissipation that needs to be concidered, but the
working voltage.
A 'perfect' capacitor doesn't disipate power anyhow because the voltage
and current are always 90deg apart. ie peak-voltage/no-current,
peak-current/no-voltage
As nothing is perfect, they will dissipate some power.
Also try Porcelain capacitors from 'Dielectric labs'.
They do a 'C40 power' range designed for high power very low loss RF
applications.
1pF to 5nF, 500V to 3.6KV, ... nice

Pure sale, no bidding wars.

Summer cleaning out the shack: several items
(terms at end)

1. (dead on transmit) RF Concepts, RFC 2-317 (2 meter brick amplifier), 30 watts drive, 170 watts output. The transmit side of the amp is dead (looked like power transistors gave out over a few minutes of transmit way back and I never tried to locate someone to fix it; the receive GasFET preamp still works). The manual goes with the brick amp. The schematic says the power transistors (assuming that is the problem) are SRF3897 and there are two of them. Schematic looks like two in parallel (many other transistors, too). RF Concepts went out of business some years ago but maybe one of you guys who knows this stuff would like to have a crack at this repair job. $10 for this unit.

2. Two Hamtronics receiving converters, CA-28 and CA-144. One takes input at 144 - 148 and converts down to 28-32 mHz (and I put a 9 volt battery case inside, and small toggle switch), the other one takes 28-30 mHz and upconverts to 144-148 mHz (I was meaning to listen to 10 meters FM repeaters with my 2 m HT but never tried it). These units do not have as low of a noise figure as the best scanners and newer ham transceivers. Both units to the same address, $35 for both. Otherwise $20 each. With manuals and documentation.

3. Yaesu YS-500 in line wattmeter and SWR bridge for 140-525 mHz. Looks fine, works fine. Max power: 200 w. With one sheet "manual" $30.

4. 440 FM Yagi, 10 elements. I think it might be a Hygain but can't remember for sure. No manual or documentation. It was never outside of an attic. At old OTH it was aimed at one 440 repeater (at present QTH, I have way too many trees and barely can get into one 440 repeater that almost no one uses, so it goes 'on the block'). $25.

---non ham electronics------

5. OPTIMUS (Radio shack) AM/FM STA-795 solid state receiver, with manual and documentation. Works fine. $20.00

6. Night vision device: NV-100/NV-100-1 by Moonlight Products, bought through Edmund Scientifi when it was in business. I need to test it at night before releasing it. I think its a first generation device. Has a large telephoto lens with low f/stop, includes manual and documentation. Runs on two AA batteries, and has its own IR diode light souce if one wants to try that. Has not been used for maybe 7-8 years, but worked fine at the time, and was always stored in a stable non-moist room at RT. Was

not used much when it was used (maybe 1-2 hours, total). I seem to recall reading that these units undergo some deterioration in performance with time, but I don't know if that is independent of whether the units are used or not used. $40

7. Panasonic AG-1830, Video Cassette Recorder, Pro-Line, commercial grade. With manual. Used a lot back 10 years ago, not much since then. It has an on-board frame-grabber, but I have lost the remote control which is how the frame-grabber was activated. Complex controls and relatively thick manual. 17 lbs. Some dust here and there. I have not extensively tested all functionalities, but besides the missing remote control, it was recording and playing back last time I used it. But if you want to receive TV signals and record them, you may need a preamp because the input is normally not very sensitive. I was in a fringe area and got noisy images unless I used a TV receiver preamp. New price over $1000. My price $55

8. Hitachi VHS video camera (portable), VM-2500A, with dead lead-acid gel-cell battery (will not hold charge, won't accept charge). Camera (color) still works fine and records audio, too. It runs fine with an external DC power supply of about 9.6 volts 2.3 amps. This is an old style, over the shoulder unit. With manual and documentation, and some cables (can take output from camera, in playback mode, and feed into a video imput device). I think its never had more than about 20-25 hours of running time. My price $30.

Terms:

If you are interested, send email. I prefer to sell in the continental USA. I prefer to ship USPS, but UPS may be less risky in terms of damage. I prefer USPS money order for sum. Sum needs to include shipping charges which I will estimate, and I'll refund any excess if there is excess. If you want insurance, I'll include that in price. No charge for packaging, handling, which will depend on what item we're talking about and I'll do my best to locate packing materials, especially on biger & heavier items. If we go with USPS, I will spring for delivery confirmation and email you the DC number. You'll need to send the money order first.

I am located in southern Delaware. Please wait a few days before expecting a response. In the event more than one person wants the same item, I will work with the first one and tell the others that they are "backup" buyers in case the first one backs out or something. You need to specify how fast you want the shipping to be; UPS and USPS have several grades of service speed (faster is more expensive). If you have a counter-proposal, I'll consider it. Please give you "ship to" address in your first email to me. On the non-ham gear, I will probably "check" the unit to make sure it is at least minimally functional before shipping.

Art, W4PON

3377. Are you interested in Ham Radio? Don't be fooled by the Lizards! Here's the FAQ!

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-06-23 17:12:12 UTC
From: Confused <radio.ham@lycos.co.uk>
Message-ID: <1151082732.090134.164780@m73g2000cwd.googlegroups.com>
Source record: 11578

A necessary preface.....

(It is becoming increasingly difficult to fly the flag for
decency and for civilised behaviour in Radio Hammery. Even
the Usenet newsgroups dedicated to the cause have degenerated
into a hotbed of abusive onslaughts by those who ought to know
better; the Nugatory Numpties who boast of an interest
exceeding 10, 20, 30, 40 or even 50 years and yet who have
proved themselves incapable of even meeting the trivial exam
standards set for 6-year-olds. However, there still exists
the fundamental basis on which Ham Radio is based, and
that will never die. This FAQ ("What Is Ham Radio?") will
be regularly published and will not be shouted or bullied
down. It is important that those of a technical bent, who
are the natural seed-corn of Radio Hammery and who
gravitate towards us to be the real novitiate, can
still find us, (and know that we are still here), their fellows.)

-----ooooo-----

So,.....What is Ham Radio?

Ham Radio is a technical pursuit for those who
are interested in the science of radio wave
propagation and who are also interested in the
way that their radios function. It has a long-standing
tradition of providing a source of engineers who
are born naturals.

Ham Radio awakens in its aficionados a whole-life
fascination with all things technical and gives
an all-abiding curiosity to improve one's scientific
knowledge. It's a great swimming pool, please dive in!

This excitement causes a wish to share the experience
with ones fellow man, and shows itself in the
gentlemanly traditions of Ham Radio.

Radio Hams are in a unique privileged position in that
they can construct and operate their own equipment! No-one
else has this privilege. Users, such as broadcasters,
the po lice and armed farces, CBers and mobile phone
users have to purchase ready-made gear. Manufacturers
are not licensed to operate their gear. Radio Hams

are qualified to design, build and then
operate their own pieces of equipment. They do this
with gusto, and also repair and modify their own
equipment. This is a privilege well worth the effort
to gain, and one to be jealously guarded.

The excitement that drives a Radio Ham starts with
relatively simple technologies at first, perhaps making
his own Wimshurst machine and primary cells. Small pieces
of test equipment follow, possibly multimeters and signal
generators. Then comes receivers and transmitters. It is with
the latter that communication with like-minded technically
motivated people takes off. The scope for technical
development grows with the years
and now encompasses DSP and DDS. There is also a great deal
of excitement in the areas of computer programming to
be learnt and applied.

The technical excitement motivates Radio Hams to compete
with each other to determine who has designed and manufactured
the best-quality station. This competitiveness is found in DXing,
competitions and fox-hunts.

-----OOOOO----

However, beware! A Ham Radio licence is such a
desirable thing to have that there are large
numbers of people who wish to be thought of
as Radio Hams when, in fact, they are nothing
of the kind! Usually such people are a
variation of the CB Radio hobbyist; they buy their
radios off the shelf and send them back to be
repaired; they are not interested in technical discussion
and sneer at those who are; they have no idea how
their radios work inside and have no wish to find out;
they are free with rather silly personal insults.

These CB types engage in the competitive activities
with their Cheque-Book-purchased off-the-shelf radios
in a forlorn effort to prove that they are Radio Hams.

No _REAL_ Radio Hams are deceived by such people!

-----ooooo-----

One infallible way to disambiguate the CB Radio Hobbyist
from the _REAL_ Radio Ham is to solicit their view of the
difference between CB Radio and Ham Radio. A Radio Ham will
perceive Ham Radio to be a technical pursuit and will
perceive CB Radio to be a social communications facility
no different in essence to a land-line telephone or a
GSM mobile in the hands of a 6-year-old. Thus a Radio Ham
could also hold a CB licence safe in the knowledge that

such a licence says no more about him than having a land-line telephone, whilst continuing to regard Ham Radio as a separate technical pursuit.

A CB Radio hobbyist, on the other hand, sees no difference between a Ham Radio licence and a CB Radio licence. To him, they are sisters-under-the-skin. Wrongly, the CB Radio Hobbyist then tries to classify himself as the equal of the Radio Ham when, in fact, he is nothing of the kind.

Ham Radio is not CB Radio and has no common ground with it! Ham Radio is _THE_ technical pursuit for gentlemen; CB Radio is the operating hobby for those who buy their rigs and equipment off the shelf.

-----ooooo-----

If you are the sort of person who is motivated by a technical interest in how things work; if you took apart malfunctioning clocks, toasters and the like and put them right despite never having seen them working, then a Ham Radio licence is your traditional route! There has never been a shortage of such people, and those who gravitate towards such an interest have always been welcomed into our shacks and their interests fostered. There is not today, nor has there ever been, a need to go out and encourage and press children, children who have never expressed an interest in Ham Radio, to come into our shacks. Such an activity should cause eyebrows to be raised - what normal well-adjusted adults seek the social acquaintance of children?!

-----ooooo-----

Please remember that this FAQ is a _POSITIVE EXHORTATION_ to you to exert yourselves to join our fraternity! (If you find otherwise, then perhaps you are already classing yourself in the mediocre groups of those who are criticised in the FAQ and from whom we _MUST_ dissociate? If so - it's never too late for a re-taxonomisation on your part - there's nothing elitist about us, and we welcome all those who are prepared to put themselves out in order to join our ranks!)

(major snippage)
That's absolute bullshit. I build and modify my own CB equipment. I know of hams that don't even know ohms law much less how to build equipment. I see lots of off the shelf ham gear for sale proving that your post is nothing more that propaganda. You perpetuate the myth that CBers are too stupid to obtain a license, you are wrong.
You post this to continue the rift between hams and CBers, fine by me, many CBers become hams, others like myself avoid it due to closed minded thinking like yours. Maybe if hams openly welcomed CBers into the fold instead of constantly insulting us, the ham radio hobby will survive. Instead the CBers will sit back and laugh as the FCC sells off your bandwidth to the highest bidder. We DO have a common ground, you just refuse to see it.

In the UK they have an M3 callsign....

Don't hold your breath on that happening any time soon!

> Instead the CBers

Well, considering the original poster posted with a .co.uk e-mail address (where he lives as he constantly pollutes the uk.r.a group), I would like to see the FCC trying to sell off the spectrum in the UK!!!!!

The FCC no longer control the radio spectrum in the United States
either. See http://www.watleyreview.com/2004/102604-2.html

Well considering that the U.K.is the U.S.A.'s lap dog, when the spectrum is
sold here it will also be sold there.

Besides, it will be a great day when the code is dropped......the rush of
the dumb CB'er onto the bands will be funny as hell to watch.Couldn't happen
to a finer bunch of assholes.

Well let's see, the original poster said the voltage across the grid
resistor seemed wrong, (leaky cap is possible there) and he said the
current kept going up and up (leaky cap getting worse with ambient
heat from the tube) and a blue glow which I find to be typical with
many tubes of the 807 style when there is excess plate current such
as may be caused by A LEAKY CAP between the control grid of the 807
and the previous stage plate voltage. Gassey tube causing runaway,
yes in circuits with high ohmic value grid resistors which is why the
d.c. impedance of power output stage grid circuits is usually low
and and includes an rf choke to keep the rf impedance high. Then, even
with a gassey final power output tube the output stage will be less
likely to run away even with a crappy tube. The original poster
added that after his experience with the runaway tube it seemed to
glow even bluer, no doubt!!!! Guess he liberated even more gass from
the internal overheated elements such as may be caused by 'a leaky
grid coupling cap' in a high resistance grid circuit connected
to a power output tube that is a bit gassey and may be experiencing
such positive grid voltage excursions during peaks causing the
grid to heat and become an even better emitter of electrons causing
a chicken and egg roundabout until the death of a slightly gassey
tube which will find it's final resting place in a landfill beside
some misfit unwanted LEAKY CAPS that I have personally cut out of
some older Seeburg jukeboxes with a problem exactly like the one
the original poster was describing.

(see original post farther down)

Update (as of 7:40 pm): I have a pending deal for the night vision scope
and the RFC brick amplifier. If the deal with those interested parties
falls through, I will make an re-announcement.

I forgot one more item: a single pan, digital balance (transistorized),
Its an "Ohaus" model C305, and reads in grams or ounces. It has a
calibration weight (300 g), a wall plug transformer supply, and can run
off an internal 9 volt standard transistor battery. And, yes, the manual
comes with it. It also has a button for "tare" weight (eg. put an empty
container on, press "tare" and it re-zeros the digital readout. The pan
comes off the unit for shipping, and just drops on. I was using it to
weigh letters and small packages. Now I have some new scales for
that. My price: $20.

Fine but he already said he'd checked it and it's not that.

No matter.

Graham

I don't think your going to see that big of a rush. What attracts a lot of
people to CB is price. I don't want to spend a ton of money on ham gear and
I don't have the time to build it. I think all that will happen is that the
lower portion of 10 meters will get the traffic with all of the "export"
radios in circulation.

> Bruce in alaska the last of the Cannery RadioMen, in alaska........

Bruce,
Wish I could remember the name of the cannery tender for
Whitney-Fidalgo that used to pass through Anacortes for provisioning and
last minute work each spring. You probably met her at times. She was some
sort of WWII conversion with a whole processing crew aboard. In the radio
room was some sort of Northern Linear that stood about 6 feet tall as I
recall. Had a pair of 4-125's in the final that would run pretty red on a
long "fooooooooooouuuuuuurrrrrrr, fooooooouuuuuurrrrr". Was driven by an
upgrade transceiver, one of my favorites, N550. (they glowed a little too,
if you tuned it for maximum smoke!)
Filament was out on one 4-125 one spring, and so in replacing with a
matched pair, I ended up with a slightly used 4-125 which I though would
someday be on 40 cw. Still in box, sob.
I used to try to keep FCC happy with responses to off frequency
operation with N-550's from three local canneries and the Texaco marine
station on March Point. Wasn't it "Northwest Crystal" that used to try to
make oven xtals that would last for almost a year on the higher bands?
The glow I remember was from a home-brew linear using push-pull
parallel 304TL's driven by the infamous BC-610. Don Knutzen here in
Anacortes would melt the snow and ice off his antenna and 600 ohm open line
feed with such a rig. Garage door openers were really new in those days, and
he was known for running them up and down all over the neighborhood Sunday
mornings.
But I digress.
Old Chief Lynn

You'll get no argument from me. The US tends to do as they please regardless
of what the rest of the world thinks.
I remember a time when most countries liked the US and it's citizens, but
those days are long gone.

I wouldn't go that far, but the FCC all but quit policing 11 meters back in the late 70s. A couple of years ago the FCC gave local law enforcement the power to enforce the laws governing 11 meters, but most of the police in my area have no interest or knowledge to do anything about it. I have a better chance of getting in trouble spitting on the sidewalk, and I don't have a sidewalk as I live in the sticks.

Yes, that post was missing on my newsreader, as were several of
the replies. WinVN newsreader gets kind of weird like that sometimes.
When I posted the first response I had only seen about half of the
total replies that were actually posted. The op's statement that
the problem follows the tube shows two things, the tube is gassey
and the grid circuit resistance is probably to high. Some of my
old books show 47k as the maximum recommended control grid
resistance. Low d.c. grid circuit resistance helps stabilize
the runaway tendancy in power output tube circuits.

Just as a compare/contrast:

With 100K grid resistors to the bias supply, the current through the resistor to a "GOOD" tube is zero. Less than a millivolt drop across the grid resistor.

And with the "BAD" tube, the current through a 47K resistor to -25V bias is so high that the drop across the resistor goes from 0 at poweron to 5V after 10 seconds, and steadily increases over the next 30 or 40 seconds to the point of 300-400mA plate current (at about 0V on the grid, and 25V drop across the resistor) when the B+ fuse blows.

So, as I see it: with a good tube it doesn't matter much what the exact value of the grid resistor is. With a bad tube it doesn't matter much what the exact value of the grid resistor is.

Tim.

Have you looked at the 44.545 MHz injection signal with the spectrum analyzer? What do you see there? Any spurs on it? I'm not exactly sure how you have it set up...are you saying you have disconnected the output of the 1st mixer so that it doesn't reached the 2nd mixer? If so, what does the 44.545 signal mix with to get the 455 KHz 2nd IF? Also, if the input to the 2nd mixer is simply disconnected, is the input port of the 2nd mixer terminated somehow? Also, are you feeding the proper level of 44.545 to it (not overdriving it are you??)? Not sure what level is required for the SBL-1.

You have spurs on one or both of the inputs to the SBL1. Passive
doide mixers will not generate spurs like that though they may pass
them through if the sources are dirty.

Also the IF could also be oscillating and your see ing that
contribution. If its the 100db IF duscussed before, thats a lot of
gain and I'd hope its bypassed and shielded very well.

Yikes!

100dB?

I suggest you use a modern mixer IC like Analog Devices AD8343. You can achieve -50 to -57dB harmonics rejection with these mixers and each mixer presents a gain of 7dB as well.

Either the LO is dirty and your not seeing it due to overdriving the
analyser or the stages after SBL1 are dirty.

What I'd expect with the input of the SBL1 terminated and the LO
applied is the LO (40db or so down) some second and third harmonic
also way down and if you go far enough down some noise.

>Maybe it is on the LO itself, but looking at the LO on the analyser it
>looks OK to me.

Ok whats at the output of the SBL1? Or more specifically whats
between the SBL1 and the Analyser?

Allison

is this FM or AM/SSB/CW?

IF FM the 100db amp will be limiting by time the input is around
10uV.

IF AM/SSB/CW you should be seeing AGC voltage developed
by time the input is 10uV (50 at the extreme max).

I suspect the 20db 1st IF is not happy. FYI those 45mhz filters
are fairly wide (usualy 15khz or more). So any selectivity
is developed in the latter stages (your MF). However the
problem is you can easily be overloaded by strong close
signals by then.

>Is that right?

Depends on the answer to the question.

>Many thanks,
>John.

A couple of observations.

If you simply disconnected the second mixer from the 1st mixer then it sounds like you do not have the output of the 1st mixer properly terminated. Unless, that is, the spectrum analyzer provides a good 50ohm termination in the probe. The SBL-1 is a double-balanced mixer but in order to get the "balance" to work right you must properly terminate *all* ports. Otherwise all kinds of impedances can be "thrown" back to the other ports - causing all kinds of problems with attached LO's and RF stages.

Regularly spaced spurs from DC to 455khz does not sound like spurious mixing products. It sounds more like an oscillator being driven into saturation causing square waves to be produced which are providing regular harmonic outputs. This could be a product of poor terminations on the mixer ports.

Directly connecting the output of a SBL-1 to the input of another mixer, even another SBL-1, is not recommended either. The SBL-1 does not have built-in terminations. A good, symmetric, 50ohm 3db pad between the stages would provide a much better setup and would not significantly impact your overall noise factor. Be sure and connect your spectrum analyzer to the far side of the pad.

This maker (and others) do broadband transformers in DIL packages.

Some of these (especially those used in twisted pair/Ethernet) very commonly show up on the surplus market.

It would be interesting to repurpose them for ham use (e.g. the 88mH toroids from the NA Bell system in the mid-20th century.)

Tim.

Hi Tim,

thanks for prompt reply.

In this case as it could be a passive device, I will try to
find the pinout by a ohm meter.

Bye

Tim, the LO is 45.455 (or 44.545) either way there should be no LF
outputs from the mixer below the LO injection unless it's a spur on
the LO.

>Directly connecting the output of a SBL-1 to the input of another mixer,

>side of the pad.

Thats true though his testing is with a 20db IF after it and one would hope that does present a 50ohm match to the IF port. Usually if the poarts are badly matched the mixing spurs are greater and the port to port isolation go to pot. If the only thing going in is the LO then likely the LO is the source but if there is gain flollowing then the gain stage is also suspect.

I've worked with enough SBL1 and MD108s and all their similar DBMS to know the SBL1 in this case is not the offendor Even if misterminated. Likely causes are the 45mhz filter is looking reactive to the IF amp and the IF is unstable (makes a fine OSC) or there is some other source of RF that is unaccounted for (spurs).

Maybe or the filter is stripping off out of band oscillations.

Try 33ohm in the base lead. IF an emitter follower is oscilating
I'd syspect layout has it looking like a VHF colpits osc. Any
layout will oscilate if the effective gains is >1.

Thank you all for being pacient with me and my stupid questions.

Another thought has just raised its head.

I have 2 IF amps. 1ts with approx 20dB gain, second with 100dB gain.
The first IF has a XTAL filter at 45MHz.
The second has the collins mech filter at the beginnig, then 100dB gain,
straight into a diode detector.

I think I need some form of additional filtering at the output of the
second IF, before the detector, to reduce the noise introduced by the
100dB amp, else it don't work. Except for strong signals.

Is that right?

Many thanks,
John.

Andy writes:

This is a 3 pole low pass filter. The type (butterworth,
chebychev, bessel, etc)
is determined by the component values, as are the frequency , skirt
selectivity and impedance.
Look in the ARRL handbook for typical configurations and
values....This
filter can also be used to transform impedances, although when that is
done
you leave the "type" classification and become more just a low pass
impedance transformer.....

It ain't rocket surgery, but if you aren't into LaPlace transforms,
you need
to stick with the tables.... or the simulator.....

The cap connected to the 200 ohm output is just for coupling and
is
usually really big, but, in some cases , may be made small enough to
provide a small breakpoint for high pass but at a frequency
considerably
lower than the low pass passband.....

If you use PSPICE , or equiv, to simulate it, you can learn a great
deal...

Andy wries:

Exactly. The noise generated by a 100 db amp with a fairly wide
bandwidth with be great compared to the noise which is admitted thru
the narrow bandpass filter in front of it, and will probably be the
major
factor to the noise floor of the system..

Do NOT use the canned Noise Figure programs in a case like this
since they usually do not consider the bandpass of each individual
element..... You have to write your own. It ain't rocket surgery, but
canned programs have their limitations...

It is a very poorly designed receiver that has a high gain wide band
amp following a narrow filter...

Optimally, two narrow filters should be used --- one in front of
the
high gain amp to prevent interference and intermod from out of band
signals, and a second narrow band filter to keep the noise from the
high gain amp from reaching the detector.....and set the noise
bandwidth of the sytem...

In practice, filters are often distributed thru the gain of the
amplifier
to keep the noise bandwidth down in addition to stopping out of band
signals. Using two narrow band crystal filters is much more

expensive.

In my homebuilt receivers, I use the two xtal filter approach, and never
have a problem. But I am building one of a kind, not for production, and
don't mind spending a few more dollars in parts.....

But, again, yes you are correct in your analysis.... 100 db is far too
much gain to put in a wideband amp feeding a wideband detector for
keeping the noise floor down...

Regarding FM versus Am ---- noise floor is noisefloor... A high noise
floor will degrade FM as much as AM.... Limiting does NOT buy higher
sensitivity, since if the noise causes most of the limiting, the phase noise
introduced to an FM detector is just as bad as the amplitude noise
put into an AM detector..... One small, insignificant exception is a possible
5.6 db SNR improvement if the FM signal is wide band, but in narrow band
FM signals the SNR improvement is negligible.....Remember , you can't
tell narrowband FM from AM on a spectrum analyzer ---- the sideband
levels are about the same..... Fm starts having an advantage only when
you start adding in the extra sidebands (see Bessel function chart) since
the FM sidebands are coherent and the extra noise is not --- this is
an advantage that wide band FM has......

I put a ceramic filter after my last AD603 amp, and bingo!!! I get quite good reception.

I think the 2 off AD603 with no output filtering was swamping the diode detector with the noise floor level.

However, the detector is buffered from the filter through an emitter follower, and guess what it oscillates at 170MHz.

How do I cure this?

Has anyone seen an emitter follower oscillating before?

3426. Filter type

From: john wilkinson <johnwilkinson@clara.co.uk>
Message-ID: <pan.2006.06.29.18.17.52.418843@clara.co.uk>
Source record: 11519

Hi,
When I was looking at an IF amp in the "Experimental mathods in RF", I
noticed a filter I have not seen before.
I will try to describe:

200 Ohm i/p impedance feeding 1 cap. The othe side of the cap feeds
another cap down to ground and an inductor. The other side of the inductor
has a cap down to ground. The junction of the ind and cap, has another cap
feeding a load of 100 Ohm.

When I simulate this it is a bandpass filter.

What do you call this filter, and where can I find some info about it?

Thanks,
John

Most of these IF xformers have a fixed capacitor on the bottom of the
device. You can remove it, measure it's value, and place a capacitor of
a slightly lower value in its place.

I've met very few that would not tune that far. It's easy enough to
test beforehand if ther eis uncertainty.

3430. Mosfet RF Amp "sprogging"

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-06-30 01:20:52 UTC
From: David <dhuisman@bigpond.net.au>
Message-ID: <U%_og.18623$ap3.1668@news-server.bigpond.net.au>
Source record: 11531

I am currently experimenting with construction of my first Dual-Gate
Mosfet Amp.

Below is an attempt to explain the circuit typology as best I can

Freq = 148 MHz to 152 MHz

Power supply is 8V, Bias on G2 is 4V. Source is grounded

Drain has Variable inductor to Vcc and Cap to ground to form first stage
of a double-tuned circuit. This then couples through a small cap to the
second half of the DTC.

RF input to Single tuned circuit with tapped capacitors attached to G1
of BF998.

C1 to ground is 56pF, C2 to G1 is 15pF, L from G1 to ground is variable
with nominal inductance of 85nH (tunes 75nH to 110nH), Q approx. 100

The Drain has the same type of inductor to Vcc (decoupled Vcc end).
C3 is 18pF from drain to ground (This forms part of the double-tuned
circuit on the output).
Coupling to second half of DTC is 1pF. Second half of DTC C4 = 18pF to
ground and L is same as previous inductors (85nH nom.).

This will later go to G1 of a Dual-Gate Mosfet mixer but for testing I
replaced the 15pF on second DTC with series 18pF and 56pF to form a
capacitive divider down to 50 Ohms for my spectrum analyzer input.

With this configuration the circuit will oscillate on its own when the
input is removed. If I replace the Capo from drain to ground with a trim
cap I can adjust it so the self-oscillation stops but as soon as I try
to change the tuning of the inductor from drain to Vcc, it starts to
oscillate on its own.

If I remove the cap from drain to ground altogether, the oscillations
stop but I almost the ability to tune the Inductor, it becomes extremely
broad tuning.(The input inductor and output DTC inductor tune fine though).

I have tried a series 33R between the Drain of the mosfet and the
Inductor/Capacitor and this did not help.

The measured gain with the capacitor removed was 17dB. Drain current was
4.8mA. 3dB bandwidth was 3.2MHz.

The circuit is laid out "dead-bug" style on a flat bare PCB. I'm not
sure if it is a layout problem or typology issue.
I have seen damping used across tuned circuits in output stages of

rf amps and may try this next. But, I would like to know what is happening because if I manage to stop the oscillation, I am not sure if it is marginal and will reappear with changes in temperature or drive level etc.

Any help much appreciated.

Regards

David

Usually DGFET amps are stable. But they are also very high
gain.

The likely culprit is the input can see the output (incidental
coupling). I always build this with a shield partition right across
the device and also a ferrite bead in the G2 lead near the deivce
as possible (or for SMD in the Source leg bypass cap). These
devices will take off at uhf due to gain and less then careful
bypassing. That includes making sure the G2 bias resistor
(Gate to DC source) does not couple RF back. As part of this
also insure the input and output leads to the connector are short
as possible or even coax.

Allison

Your bypasses from G2 to ground and from the top of the drain inductor to ground should be physically small, have very nearly zero lead length, and connect directly to the drain or the bottom of the drain resistor if used.

Thanks for the feedback (no pun intended :) I appreciate it.

I will add a shield between input and output circuit. I do remember seeing this in other designs. In my prototype construction I do have the input and output coils fairly close and in the same orientation so I imagine there very well could be coupling between them.

the fact that the circuit oscillates very close to the tuned frequency is probably a clue that positive feedback between input and output is happening. The source is grounded so Drain - Gate seems feasible.

I will also take the advice of adding a ferrite bead between G2 pin and the voltage divider for G2. (Currently 100k+100k with 1n decoupling).

Can anyone suggest a reasonably simple method to determine noise figure of this stage ? I do not have a distortion meter. I have directional couplers, sig gens, sepctrum analyzer and digital power meter. Can I use these somehow ?

Thanks in advance again

Best regards

David

Source record: 11537

I have applied the suggestions and still can't manage to "tame the beast".

As long as the cap to ground from drain is in circuit the amp becomes
unstable at oscillates close to the centre frequency.

If I remove the cap the amp settles down but I loose tuning of the drain
circuit and the gain drops down.

I have a picture of the layout and schematic if anyone would be prepared
to take a look and see if there is something obvious.

The shield is placed right across the top of the BF998 to separate input
from output.
All component leads are cut as close to the component body as possible.

I also added another shield between G2 and the input circuit so the
input now is totally isolated from the rest of the ckt

Regards

David

3437. The beast (Dual gate Mosfet RF Amp) is settling down

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-06-30 06:28:17 UTC
From: David <dhuisman@bigpond.net.au>
Message-ID: <5w3pg.18735$ap3.2463@news-server.bigpond.net.au>
Source record: 11538

I have conducted further investigation and discovered the following

1. Coupling between tuned circuits in DTC was a little high (reduce this from 1pF to 0.5pF)
2. The Cap from Drain to ground (1st tuned ckt in DTC) was a little large. Reduced this to 10pF from 15pF.

These changes enable smooth tuning of each inductor without any surprises. Gain has shot up to around 24dB and 3dB bandwidth is around 3.5MHz at 151 MHz Fo.

What I do notice is that when I remove the input cable from the signal generator, the circuit starts to oscillate. If I terminate the floating cable with say a 6dB attenuator, the oscillation stops.

Should I have something in front of the Single tuned input circuit such as a RFC, 3dB resistive pad or LPF to define input impedance ? Or is it maybe just the input floating as the Tapped capacitor divider has nothing to ground on the input side (FET side of course has the inductor to ground).

Thanks

Regards

David

I had a similar problem with a 2M RF amp. I cured it by
reversing the winding direction of one of the inductors.

> Can anyone suggest a reasonably simple method to determine noise figure
> of this stage ?

I'm a bit reluctant to suggest a method that I haven't tried
mysef, but you should be able to calculate NF by measuring the
receiver noise output with a hot and cold resistor connected
to the input. The usual method involves boiling water and
melting ice. http://tinyurl.com/psdfo

What kind of spectrum analyzer are you using? What are the front end attenuator settings on the spectrum analyzer? What is your reference level? All of these things, especially the front end attenuator settings, can affect your result. If the 1st mixer in the spectrum analyzer is driven into nonlinearity, you can see all kinds of IMD products that are generated in the analyzer itself.
Also, why are you doing this test with the RF port of the mixer terminated in 50 Ohms? This type of termination is only used when doing either return loss tests or noise balance tests.
If you are driving the SBL-1 mixer with +7 to +9dBm of LO level and you are driving the RF port with a signal that is at least 20dB below the 1dB compression point of the SBL-1, the main things you should see at the I.F. port are a supressed LO signal, an upper sideband that is about 7dB lower in level than the RF injection level, and a lower sideband that is also about 7dB lower in level than the RF injection level.
The 1dB compression point on the SBL-1 is about 0dBm, so I would set the level to the RF port at -20dBm. If you go above this level, you will see higher conversion loss, and possibly more IMD products at the I.F. port of the mixer.
In conclusion, make sure that the IMD isn't being generated in your test setup, and make sure that you are not exceeding the recommended RF input level to the SBL-1.

David,
I don't know your technical level, but here goes. I thought the dual gate is a type of cascode arrangement and should be stable owing to the isolation of the "top" device... Anyway...

You are very correct about trying to "band-aid" it with de-Q'ing resistors. You need to find the root cause, not hope a patch works. You are well aware of and trying to solve a possible proximity feedback issue, so I won't go there.

It is not clear what your term "sprogging" may mean. There was a term "Squeeging" which referred to oscillation or what is also called regen(regeneration) which is typically used for dirty (sideband-type), rather than clean (single frequency) oscillation.

Is the oscillation a clean, oscillator signal (pure carrier), or does it have sidebands?

If sidebands, are they clear and distinct or is it more of a wideband grunge/garbage?
Are the sidebands mirrored on both sides or are they lopsided?
These are all clues.

If you have regular sidebands or grunge, you have a low frequency oscillation component and need to also look at bypassing. 33-200 ohms or a ferrite bead in series with a bypass can help diagnose it.
If the sidebands are unequal, there are most likely both AM and FM components to the oscillation. Putting a regular scope on the supply or other places which are supposed to be bypassed might see the signal, helping to ID the cause.

Be aware that two bypasses in parallel, of different size, can become a tuned circuit and therefore a high impedance at frequencies where the larger one is above self resonance and appears inductive.

Pay extreemly close attention to the ground currents for the input and output circuitry. You want to have an absolute minimum of common path for these. I didn't see anything in your circuit description about the FET source. If it is self biased with a resistor & cap combination or what, but from the source you should have two distinct paths in the ground you have to the respectice components tith no length of this "ground current path" in common - where both currents share a common path. you can even cut the PCB so there are two distinct ground planes which only meet at the FET source or its resistor/bypass cap.
Watch the power supply side pretty much the same. Where does the Drain bypass connect to the plane?

Hope this helps.

Body handling: HTML body converted to readable text

This didn't sound like the problem if I read it correctly, but...
To test for analyzedr generated effects, switch-in 10 dB of attenuatin in FRONT of the analyzer mixer (not in the analyzer IF). If the garbage drops more than 10dB (like 20 or 30) then you are over driving the analyzer. If it is coming from outside, then you'll se dB for dB changes.

73, Steve, K9DCI

Ain't the math of nonlinearity great?

A quick test for spurs being generated by the spectrum analyzer is to increase the spectrum analyzer input attenuation by 10 dB. Real spurs will drop 10 dB. Most spurs generated by the analyzer will drop a greater amount -- 20 dB if they're second order, 30 dB if they're third order, and so forth. If any spurs do drop more than 10 dB, you have to reduce the SA attenuator setting or the input signal level to the SA -- at least the level of the signal(s) generating the spurs.

Source record: 11544

Hi Everyone,

I hope to get my technician license for the first time in a month or two, and I've been thinking of setting-up shop in the garage once I start getting some radios and equipment.

Some questions though, the garage is on the corner of our brick house with one smaller window (facing front of house), two walls are interior walls with other two being exterior (one having garage door).

My thought is if I insulate the attic and the one exterior wall without the garage door then replace my aging garage door with a better sealing one, that should do the trick -- right? As for heating and cooling, i'm in central texas, and our summers do get hot. I don't think our A/C in the house could pump out enough cool air to cool an additional 430sqft, so any suggestions for that? The only window is on front of house, so don't want to use window unit. I have a radiant heater I've used in there for winter, and it works well.

Thanks for any suggestions or ideas ... we don't park our cars in the garage, and I hope to build a small shead in the back yard for the mowers and such -- so that's 430sqft of space that's going to waste.

Thanks again and take care ---

Alex

3444. Self-heating of crystal in inverter oscillator

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-06-30 20:48:03 UTC
From: Ben Jackson <ben@ben.com>
Message-ID: <slrneab3g3.9if.ben@saturn.home.ben.com>
Source record: 11545

I've got a 74HC86 (quad XOR) and I'm using 2 of the gates (with one input tied high) to make inverter oscillators. One crystal at 14.85MHz in a SMT package was relatively easy to start up and stabilize. The 25MHz crystal (in a short can package) was very sensitive to Rs (series resistor between the inverter output and one leg of the crystal) and low supply voltage. To get it to start reliably I ended up with Rs=110 @ 5V. The whole thing is drawing about 25mA.

The problem I have is that the 74HC86 and 25MHz crystal seem to warm up quickly and cause the 25MHz to drop by about 200Hz. This oscillator isn't intended to be on for long periods of time, so I'd like to avoid that. I've isolated those two parts by a combination of heating and cooling components to see which contribute the most (the temp swing is too small for me to feel, I'm just warming with a finger and cooling with a puff of compressed air).

So if I'm putting 15mA+ into that crystal, is that unusually high? What would be a typical amount for such an oscillator? Is there anything I can do about the effects of chip heating (I'm assuming the gate capacitance is going up as it heats)?

From a stability factor point of view those "inverter" based
oscillators are amoung the worst. I doubt it's all crystal heating
and I bet there are parameter shifts in the "chip" as it warms up
operating at high frequency like that. Also If you drive the crystal
hard like they do (15ma!!!) bad things happen. Those circuits are OK
for micros and other less critical apps.

I suggest a discrete Bipolar or FET where you can control the
operating point of the device better.

You top posted to a reply that I'd posted to and your context is way
off as a result. Go bat to the root of the thread and read the
posting again.

Briefly, he's seeing spurs every 25 or 50 khz with a LO in the 45mhz
region and NO RF on the input (unterminated RF port).

3447. Re: Mosfet RF Amp "sprogging"

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-06-30 23:46:14 UTC
From: David <dhuisman@bigpond.net.au>
Message-ID: <aJipg.19085$ap3.13820@news-server.bigpond.net.au>
Source record: 11448

Thanks all for your input into this issue. I appreciate all the feedback I have received.

I do like to discover and understand the mechanism for this issue so I can avoid it next time.

"Sprogging" was probably not the best term to use afterall.

The unwanted response is a clean carrier with no sidebands.
This carrier appears within the tuning band of the amp tuned circuits and moves as either the input tuning
or Drain tuning is adjusted.

The Source is connected to ground plane.

The circuit now only just starts to produce a very low level signal (maybe around 60 dB down) when I unplug the input cable from the signal generator. If I terminate the floating cable with a 50 Ohm attenuator, the oscillation stops.

The most improvement has been achieved by addition of shielding between Input circuit and drain circuit.

I suspect that I am getting radiated signal fed back. I also suppose that as long as the path loss between drain and input is greater than the gain of the amp then the circuit should not be able to oscillate.

One other issue I were considering was that even though the circuit is built with very short leads directly on a continuous ground plane (PCB), Some "Pads" have been made by cutting away copper. But because the PCB is double sided, I wonder if the interaction between these pads make the lower ground plane and pads act like a capacitor (ie. energy coupled from the pads into the lower ground plane and up into other pads through capacitive coupling).

Maybe if it was single sided board or I add heaps of track pins from top to bottom layer would prove if this was the case.

Another thing is the coils do not have their own shields so they probably act like antennas. I think it would be prudent to use only shielded cans as I cannot always ensure large physical distance between them.

Regards

David

Andy comments:

I'm in Nawth Taxes near Dallas, and your're right --- it gets REAL
hot
here in the summer. You do need air condx. And to air condx a whole
garage (about 20 x 20) needs a large unit....

Here is a suggestion that you might consider.... Wall off a closet

sized part of your garage, either with cheap panelling or maybe
plastic curtains, and get a Home Depot $70 air conditioner to use
just for that part..... Also good for space heater in winter....

Perhaps you can make sliding curtains like they do around hospital
beds..... A little 5000 BTU unit will cool the hell out of a small
closet-like
area, even if it is poorly insulated and leaks like hell.... The air
condx

can be mounted on a little dolly or something......venting into the rest
of the garage. And slid off on the side when not in use...

This may not be a great idea, because you still have to get your wife's permission and it changes your garage some, but I know it would work well.... Just go into the "corner", pull the curtains round you,
or slide the panelling or sliding doors or whatever, turn on the air condx
open a beer, and start tapping out CQ...... It costs about ten cents an hour to run the little air condx, so cost isn't a big deal here......
Just shrink the size you need down to the minimum you are comfortable with ---- maybe 5 x 5 or so.....

Or maybe it's a bad idea..... just an opinion.....

I use my tornado shelter. It is small, and cozy, and doesn't need air condx much cause it is soil temp in winter or summer.... Still gets a little cold, tho.... And the wife NEVER goes there, so I can put up my Elvira posters and not get any grief......

Andy comments:

I think they will probably go that far, and you might be able to decrease the external cap 2-3% to help... ALSO, you might be able to use a brass or aluminum slug to raise the freq.... Tears heck out of the Q tho, so it's probably a last resort......

Also, you might take out the ferrite slug, grind off a little, and put it back so you can still tune it without backing it out all the way....

You may try changing the input coil (less L and more C) and see if
that helps.

>capacitive coupling).

Grount the top to the bottom of two sided boards. I use foil or braid
to wrap the edges.
Also add a few holes and put wires from top to bottom near the source

lead.

Next time rather than cutting pads in the board try this, Cut tiny
islands of PCB material and super glue them down. Then you have
isolated pads for SMT parts. For devices like BF998 in SMT I've
used board "chips" that are 0.1x0.2 inch and that works fine.

FYI when I used that device the source has a 100 ohm resistor to
ground and the bypass cap is .001(for 6m) with a ferrite bead
on the non grounded lead. That is a "stock" circuit for DG fets
and it seems well behaved to me.

>Maybe if it was single sided board or I add heaps of track pins from top
>to bottom layer would prove if this was the case.

Do the latter. If you wrap the edges and put pins through near
grounded compnents that's enough (likely only a few needed).

>Another thing is the coils do not have their own shields so they
>probably act like antennas. I think it would be prudent to use only
>shielded cans as I cannot always ensure large physical distance between

That helps.

Also make sure the output side has a valid load on it too.

Do not load or resistive pad the input as that degrades the NF and
gain.

SSB CB radios are fairly rare nowdays.

The microphone connection is non-standard, and won't directly wire to
a sound card.

A wire flung over a 3 story office building won't be matched. It will
likely work poorly, or it may even fry the transmitter.

>One of the reasons for this scenario is to lighten the overall squad

A 1 to 2 pound VHF radio will give better coverage, will function as
they are going in, and will free up personnel labor for more important
tasks.

Wasting a person's time setting something like this up is more serious
than carrying a small hand-held radio.

Carrying a 1 to 2 pound VHF radio in will provide communications all the
way in. Using it will save a lot of personnel time that can be used for
something more important that hacking together something with a CB that
would work very poorly if at all.

Conclusion: This must be a troll. I hope that nobody in our government
is *STUPID* enough to fall for such a plan.

Good to know. I was trying to reduce part count -- the quad XOR provides
the two oscillators plus one mixer.

> and I bet there are parameter shifts in the "chip" as it warms up

The other parameter shift I was missing was droop in the 5V rail as
the 78L05 warmed up (rapidly!) and noise injected by a MAX202 charge
pump also on that 5V rail. I thought that regulator was just for an
(unused) LCD header, but I was wrong.

If I can't tame this VCXO I will try that. This must be how Manhattan
prototyping branches off into "Ugly"...

What exactly specifies that the 465 kHz must be used ?

Is there a frequency synthesiser or frequency counter with specifies a
fixed 465 kHz offset ? If not, just run the local oscillator at a
frequency 10 kHz lower to produce the 455 kHz IF and calibrate the
scale accordingly.

If this is a dual conversion receiver, change the second mixer
oscillator frequency.

==========
With only having double sided PCB material I drill various holes and
bond the 2 planes at different locations by soldering wires on both planes.
For VHF/UHF circuits (in addition to the above) I line the circumference
of the material by folding 6mm wide thin (abt 0.2mm thick)copper strip
onto both planes and solder. I found a 'half a mile long ' roll of this
material at a flea market .

Thanks for your input everyone.

I re-constructed the layout using SMD components on a bare copper PCB.
This time I changed the typology slightly and added 100R with 1n in the
source of the BF998. I placed a 2k7 across the drain coil to set correct
Rp for the DTC bandwidth.

I also changed the tuning coils for fixed coils and tuned with variable
caps instead.

The circuit seems stable now. The Amp has total gain of 23dB (includes
loss of the input filter and double tuned circuit).
All caps are tuning properly with no unexpected behaviour.

I have not yet added any shielding or connected vias from top to bottom
plane of the PCB.

The tuning range is almost as calculated (6MHz Bandwidth at Fo = 150 MHz).

Does anyone know what an reasonable 1dB compression point would be for
a the BF998 at 150 Mhz ? The drain current seems a bit low (about 3mA)
and I think this may need increasing to get a reasonable dynamic range ?

The gate 2 bias is currently 4V. This should not be pinching off the
drain current at all. I wonder if the 100 Ohm in the source should be
made smaller ? Any ideas.

Thanks

Regards

David

Before you get too concerned over the amps DR you need to consider
that the RX following will be typically be degraded in DR by the
amount of gain ahead of it. That would be true for most cases unless
the RX has a IP if +10DBm or better.

I haven't meaured many of those amps for DR but 1db compression
is around a few DBm (one was at +2dbm and the other was +5dbm
output) by then most recievers are grossly overloaded.

>The gate 2 bias is currently 4V. This should not be pinching off the

FETs have good dynamic range for their current. You can lower the
100r but the increase in DR is small. You can also play with the
bias to gate 2 (go for the high current side of peak gain).

Those added elements don't help. However I've used flavors
(both TTL and CMOS) of the circuit and stability is only ok at best.
One use was a simple freq counter (commercial purchase) and I
could never get it to stay zeroed on WWV, it was always 100hz or
more off every time I'd check it. I tried everything and finally
pulled that out and added a simple transistor circuit. After than the
error was usually less than a few hz.

I'm also here in central TX and have the additional penalty in that I live in an apartment. My shack is in my car, it doesn't take up much room to install a vhf radio and an hf radio. I do have duplicates in the apartment in the event that the car is out of service. I just don't have the hf rig in the apt hooked up to an antenna full time since the manager is not ham friendly. If I want to work hf I just drive the car to the top of a hill and tune up, idling with the ac running it works just fine for the 9 months of summer, with the heater running for the 2 months of winter and with the windows open for each of the 2 weeks of spring and fall. If you are more interested in emergency operations, then tying yourself to your garage can be a negative.
thanks, John.

Andy: my answer is completely lateral thinking, but if for some reason the whole ham shcak thing at your home doesn't work out what about HF/VHF mobile from your car (with A/C of course), or join your local ham radio club that has its own station. I know from experience that many club stations often get very little use!

Good luck with your solutions...

Anything that is radiating from a "Cable Tv" cable will be FAR below the
Human Exposure Safety Level. The signal levels on those distribution
feeds rarely ever get above +10dbm and the frequency your seeing is
usually used in the "Return to Headend" direction which will have less
power than the Main Distribution Channels. The FCC has very strict
guidelines for ammount of RF Radiation allowed to leak from those type
systems, so I would contact the Cable company and let them know, but it
isn't a Health Hazard, or even close.

Jeff-

I don't know about the IEEE standard, but you might check out the FCC Safety web site at
www.fcc.gov/oet/rfsafety
and look for their Bulletins 56 and 65. In particular, Bulletin 65 describes alloowable levels and how to measure them, for various frequencies.

Bulletin 65 may have a reference to the IEEE standard you are looking for, if it exists.

I am in Central Oklahoma. It is a little cooler in Oklahoma but not much.

I built a garage shack a couple years ago. I framed a 9 x 9 room and insulated the ceiling and outside walls. I sheet rocked, texturized and painted the inside. One side is a rib-high workbench with shelves for parts, tools and my test gear. I was more concerned with the workspace but left room for an operating position on an opposite wall.

Check Ace Hardware's portable air conditioners. I have a roll-around that vents into the garage and sits in one corner on wheels. I am considering adding the house system at some time as the main unit is 3 feet from the room. However, the portable is better than I expected. These units can be purchased with heaters too.

I decided to make the room permanent. It is airtight and heats and cools well. But simple plywood and insulation would provide a good start.
Very temporary walls could be build but in my case I wanted a solid door. Also, a couple 100W light bulbs keep the room decent the whole winter at 60 deg or above.

I also have intake air drawn from a less unused portion of the house with a small one way dryer vent when I used the airconditioner. Not real efficient but I don't see the effect on my electric bill.

A little more complex but lets me use the shop during the hottest parts of the summer days.

I had always wanted a secluded room/shop of my own and I have been real happy with it. I build tube gear and its most enjoyable on those cold winter nights when no heater is needed with 21 tubes blazing away.

BTW, in my old house I merely put some heavy cloth material around the bench in the winter and used a small space heater. Totally unsafe but I was younger, dumber.....and luckier.

If it is a Toko transformer, this will typically tune from around 400kHz to 500kHz, depending on the specific component.

You are "detecting extremely high levels of 4.2 to 4.5 Mhz. RF"? How do you know?

Please give some numbers. In any units with which you are familiar.

Andy writes:

If I remember correctly, a graph is presented in the ARRL Handbook
giving the safety levels.

Just a minute --- I'll go look it up.....

Ok, from the 1992 ARRL handbook with the proposed 1991 ANSI standard,
the RF level at around 4.5 Mhz is:

For controlled environment 60 V/M

For Uncontrolled environment 30 V/M

I may be a little off since the graph isn't very big and is hard to
read....

If you need power density, just square the V/M and divide by 377 and
you will have watts per sq meter....(assuming far field0

If you need magnetic intensity, just divide the V/M by 377 and you
get amps per meter....(again, far field)

These are BIG fields. It takes a LOT of 4.5 Mhz field to hurt
you......

This stuff ain't rocket surgery..... Shucks, if big 80 meter fields
would
hurt a person, I'd have gone crazy long ago.... :>)))))))))

Anyway, more than likely these were the adopted standards. I don't
have
a more current book available....

3471. Re: Filter type

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-07-02 01:14:17 UTC
From: Pete KE9OA <p.gianako@comcast.net>
Message-ID: <GIqdncmam4J1gDrZnZ2dnUVZ_oOdnZ2d@comcast.com>
Source record: 11472

It sounds like the shunt cap on the filter end may be used for tuning out
any inductive reactance in the filter itself. The rest of the circuit, with
the series L, shunt C might be used as an impedance matching network that
would step the impedance of the filter up to a new value.
This type of arrangement, without the shunt C at the input end is a classic
way of matching a 50 Ohm doubly-balanced mixer output to a high impedance
crystal filter. Good design practice would usually have the coupling caps to
have an impedance of between 1 and 2 Ohms.
Now, if you were feeding a lower impedance load, you could look at this
network from the load end as a series L, shunt C matching network that would
match the impedance of the load to the higher impedance of the crystal
filter. In this case, the shunt C would be to tune out the imaginary
inductive term at the input of the load itself (this would be called
conjugate matching).
If you were to connect this circuit to an RF network analyzer, you would be
able to see the magnitude and the angle of these terms, but a good
simulation program such as Ansoft Designer (free) would show you what is
going on. You would need to have models of the devices in the load itself
for maximum accuracy.
That's the fun part of RF design.....the experimentation and the
learning!

Pete

Garage doors lack insulation, but you can do something about that.
I live in South Florida, and while it doesn't get as hot as in Texas,
it does get hot. We added insulation to our metal garage door in the
form of Styrofoam insulating panels slipped into the inside of the door
ducktaped in place. Fiberglass insulation with the cardboard backing
would work as well. (Which has the better R value??). You might have
to re-balance the door after adding the insulation, but in our case
the garage door opener didn't seem to care and isn't straining. The
insulation lowered the temperature in the garage during the summer by
at least 10 degrees F.

hi ham radiogroups, im after the internal power control or alc inside of a icom725 hf transceiver the radio is doing way to much power for the power supply, it currently is doing 150 watts it needs to be turned back down to around 100 watts .thanks in advance david from nsw australia .

3475. Help with Mosfet mixer

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-07-02 05:53:05 UTC
From: David <websales@orbitcoms.com>
Message-ID: <5bJpg.19786$ap3.8783@news-server.bigpond.net.au>
Source record: 11476

I have constructed a Mixer for a VHF receiver (150MHz).
The IF frequency is 45 MHz and LO is 105 MHz.

Having not made a mixer before, I copied a typology directly from one of my fundamental electronics books.

The layout is...
RF signal into Gate 2 of BF998.
Source has 100R Par with 1n to ground.
G1 has 47K to ground and 100p to LO signal (I am using a sig gen for testing).

The drain has a Tuned circuit consisting of 100nH and 125pF.
A 1k resistor is across the coil to provide approx. 800 Ohms needed to interface to a 4-pole crystal filter.

For testing I used a tap-C down to 50 Ohms from the 800R tank in the drain of the mixer BF998.

I observe the frequencies coming out of the mixer when I inject the 150 MHz RF signal and find I can tune the 45MHz for a peak no problem.
There do not appear to be any instabilities.
The gain of the preceding stages (Input single tuned filter, MOSFET RF amp and Double Tuned Circuit) is around 24dB.

When I add the mixer I find the total system gain is the same (24dB),
The mixer seems to be mixing but adding no gain or loss. I also wonder where the mixer MOSFET is getting bias (from the LO ?) because the mixer stage doesn't appear to be drawing any current. I found the max. gain at the mixer output was when the LO level was anywhere from -5 to 0dBm.

Would someone please mind explaining how the bias of the mixer should be applied and how much gain/loss I should expect. (i hope I am asking the right questions here as have no previous experience with a discrete mixer).

Thank in advance.

Regards

David

Normally this would be OT in this NG ,but mentioning styrofoam =
polystyrene , it is veeeeeeeeeeeeeeery flammable and if used in an
enclosed environment ,people inside would be in real trouble when a fire
broke out. Insulating material should be fireproof or at least flame
retardent while not emitting toxic/suffocating fumes.

Andy comments:
My garage door is of the insulated type. It has some sort of
fiberglass stuff
like you get in those 4x2 ceiling tiles.... It is redundant and I
think more of a
sales gimmick than any real barrier to heat transfer.....

Regarding roll around air conditioners..... I like the idea a lot,
but they
are very very very expensive compared to a vanilla window unit....
Home Depot sells a window unit here for about $80 USD while the
cheapest
roll around I have seen is over $300 USD for about the same size....
A crafty ham would buy a window unit and then build a little roll
around
cabinet with some dryer vent hoses to make his own. After all, most of

the fun is building stuff, even if it doesn't look like a "finished"
product.....

(I am a big fan of The Red Green Show :>)))))

I am doing something like that in my attic ---- running the intake
duct
from the cooler garage below and the air exits into the attic, which is
already

hot so a little more heat won't matter..... Not a roll around, but a ducted
cabinet....... But then I have nothing better to do all day except to mess
around with this stuff .... probly not a great idea for everybody, tho.
I go thru a lot of duct tape..........

Just my dos centavos.....

Andy in Eureka, Texas W4OAH

==========
If the current RF power output itself is not a problem ,but the max
current which can be supplied by the power supply unit (presumably
13.8V) I would suggest to put a sealed (car) battery in parallel.

The quoted 150W RF power is highly likely PEP ,so when operating SSB the
average current consumption is possibly half the peak current or less
even with some speech compression .
The battery will happily supply some of the current during peak demand.

Since the battery is permanently 'on the charger ' being in parallel
with the power supply unit , you don't need a deep cycle battery ; a
cheap and cheerful 40 -60Ah sealed car battery will do the job well.
It is essential to put a 25-30 A fuse in series with the battery .

Note : I recommend anybody to use a (sealed) battery and a low power PSU
to feed a transceiver requiring (13.5 -13.8 V-DC) external power.
During rx periods the PSU output could be (automatically) disconnected .
Receiving on battery power alone is often beneficial eg less noise and
mains borne interference. Although the low impedance of the battery
will cause it to 'kill' most external mains borne interference already.

A local ham uses a FT857 with a 110Ah sealed battery, without a mains
fed PSU . When not operating the battery is connected to an automatic
car battery charger ,which is only disconnected during operation.

Isolating a small volume from the garage makes sense since now the thermal resistance of the external wall and the closet walls are in series, thus reducing the heat leakage from the outside to the operating position and hence, reducing the heat that needs to be removed by the air conditioner.

Since the closet walls are much smaller than the garage wall inside dimensions, for a specific amount of isolation material (and cost) much better isolation can be obtained by isolating the closet than isolating the whole garage.

> Perhaps you can make sliding curtains like they do around hospital

>area, even if it is poorly insulated and leaks like hell.... The air
>condx
>can be mounted on a little dolly or something......venting into the
>rest
>of the garage. And slid off on the side when not in use...

Venting into the rest of the garage does not make sense, especially with light closet walls, since this would be equivalent to an electric or acoustic short circuit.

If you look at the situation from the rest of the garage, the heat from the closet will enter the larger garage space, as well as the power required to run the air conditioner, as well as the leakage from the outside world through the garage walls.

The rest of the garage will get very hot and if the closet walls are light, leak back into the closet, requiring more air conditioner power to remove it etc. The temperature of the rest of the garage will continue to rise, until the temperature is sufficiently _above_ the outside temperature and sufficient amount of thermal energy will flow _out_ through the garage external walls.

Two ways to avoid this problem, one is to let the closet air conditioner pump the heat to the outside air or if the heat is pumped into the rest of the garage, at least open the garage door and use sufficiently good isolation in the closet walls to keep the air

conditional power requirements at a reasonable level.

After all, air conditioning is a similar problem as thermal management in any semiconductor systems, which use the analogies with resistances/conductances (thermal isolation/conduction) and capacitances (specific heat x mass).

Styrofoam type insulating material that is designed for the purpose is
made in a fire-retardant form. You have to buy the material made for
the purpose!!!

Andy comments:

I haven't used that particular dual gate Mosfet, but I will tell you
how I have used 3n140, 3n141, and others:

G2 was used as the LO and was bias at around 3 volts DC with
resistors. The LO was cap coupled in at a leveL of about 2.5 Vrms.
It is useD as a switching signal to drive the MOSFET into and out
of conduction. It takes very little power from the LO, but the
2.5 Vrms swing was needed...

G1 was used as the RF port. G1 and the source were biased
pretty much as you described.

The drain was similar to your design. While using a 1K resistor
gives
a great source impedance to the xtal filter, it also absorbs most of
the signal.... If I remember, the output Z is 9 or 10 k for the devices
I used. I would use maybe a 7.5 K resistor and then impedance
match in the tuned circuit to get the source right. This usually took
some experimentation. Since the drain output was tuned to a different
frequency than the LO or the RFin, I never had a stability problem.
Power gains of 15 to 20 db were very common... (Note , I said
POWER gain, and not voltage gain , which could be anything...)

Maybe my experience is outdated with the newer Mosfets, but I
have never seen, or used a circuit that put the LO on G!.... It was
always on G2.. I used dual gate mosfets to build receiver front
ends and mixer from about 1967 to about 1990. Then I started
using doubly balanced stuff like SBLs and MDs ..... I followed them
with a nice amplifer and good termination.....It costs a little more,
but the designs were always more stable and gave better
performance.....

I hope this helps. Perhaps others here have used your particular
device and can give better guidance...

Ever since the Cable Company mounted a large (3'x2'x2') electronics box
on the telephone pole outside my home, I've picked up interference on
my General Coverage receiver at 4 Mhz. plus. Using my RF Frequency
Counter with 50 ohm antenna, I was able to pinpoint the source of the
RF to that box. Also, I am able to pick up the RF 400, 500 plus feet
away! Considering that the same meter doesn't pick up my cell or
cordless phone more than a foot or two away, I have to assume that the
4 Mhz. RF is in the watt range, rather than micro or milliwatts!

I noted in We Hayward's book "Experimental Methods in RF Design" that he suggests the gain of a Dual Gate Mosfet in a mixer circuit is about 1/4 of the gain of the same device in an RF amp circuit. If this is true then the 6dB gain I now see in the mixer stage would be about right.

I cranked up the LO level and now have +/- 4V on G2. I tried biasing the Gate up to 3 but it made no difference than when just 47K to ground bias was used on G2.

The main issue I am having now is matching to the 4-pole filter.
I have tried several approaches and the performance is disgusting.

The current mixer to filter circuit is....

This "should" have matched down to 800R

100nH (Q=100) inductor to Vcc from Drain
6-30p trimmer to ground from drain
Split capacitor tap from drain to ground (220pF in series with 200pF)

1st filter, 4p7 to ground between 1st and second filter.

Output match to 50R from 800R for testing...
100nH to ground from filter output
82pF to ground
6-30p trimmer to ground
15pF in series to 50 Ohm load.

The loss through the filter is around 10dB instead of 3dB, the ripple is around 6-8db instead of 1dB. The filter response shows double peaks with dip between, either side of the peaks falls off extremely quickly at around 2 kHz off (should be +/- 15kHz bandwidth).

I would appreciate any help I can get to determine what is happening and to correctly match into this filter that requires 800R//3pF terminations at 45 MHz.

I'm not so much worried about hazardous effects, it's just that I don't think the cable company should be installing equipment 50 feet from my home that is broadcasting RF
so close to the 80 meter band! I'm also tired of doing "their job" for them: last year when the neighborhood experienced problems for weeks and weeks with their Internet system, I had to show their field engineer that there was a problem on the "uplink" side of their network. "By golly gee, you're right!" was the prognosis from the back of the Cable truck....

Since everyone is top posting.

Having G2 driven hard is good for large signal handling as mixing
will occure with lesser levels. So that's why that needs to be done.
If driven hard enough bias has no effect.

I vaugely remember you saying your using two filters back to back...

If so you may have the interfilter coupling way off. Also the loss for
two 3db loss filters would be a bit higher than 6db if everything is
right.

Andy writes:

Ok. Well, using +/- 4 volts (i am guessing rms) will certainly
drive
the mosfet from full on to cutoff so DC biasing wouldn't be required.

Less LO could be used with a DC bias, but if you have the LO power
available, there is no reason to change.

I am assuming that you have gotten rid of the 800 drain load.....
The split cap approach is fine and should give you about a 4/1
step down, so if the drain output imp is 3200 ohms or thereabout, the
match should be close... (I am doing this in my head, so forgive me if

I am off by a thousandfold :>))))

Now, the filter loss is something else. You did not tell me how you

measured it, and I am assuming that you just measured the voltages
and used that. This is a common mistake as there can be substantial
impedance change. The only accurate way to characterize filter loss
is with a special test jig which can measure the power into the load
without the filter and then the power into the load WITH the filter,
without
changing any of the tuning.... A purely resistive jig with a highZ
probe
can be fairly accurate, measuring voltage loss..... But you have to
allow
for any impedance changes in source and load.......

The inter match between the two filters should have both and L and
a C
making a parallel tank to make sure both the filter reactance, and the
stray reactances are tuned out. Usually filters are slightly
capacitive
, a couple pf, on their parallel terminal impedance......a tuned
circuit
will tune all this out..... giving you 800 to 800... You tune the tank
for minimum ripple in the passband... not for max gain at one of
the ripples.... tho it will be close...

The output transformation from 50 ohms up to 800 ohms represents
a 4 to 1 voltage transformation, or 12 db voltage loss..... In other
words,
if you used an 800 ohm resistive load (with a parallel tank to get rid
of the reactance and strays) you would, with a voltage probe, measure
12 db higher than you would when you transformed the load down to
50 ohms.... If you already knew this, and accounted for it, I
apologize for
assuming you didn't,, , but it is a common mistake some people have
made....

I don't disagree with Wes's book or explanation at all, but I am
surprised
that 12 db was the best the mosfet would do.....but, as I said, I have
never
used that particular one...

Remember, you have to match the RF generator UP to the input
Z of G1 in order to calculate the conversion gain. If you have just
connected G1 to a 50 ohm RF source, you are losing a lot of voltage
since the input Z of G! is probably a couple K..... That is quite a
voltage gain.... and that is before the conversion process even
starts....

It looks to me like you are on the right track. Again , I apologize
if it seemed
I was "talking down" to you, but I am just doing an all-purpose memory
dump
of all I remember about when I did this..... And I know for sure that

I got a hell of a lot more conversion gain out of a 3n141..... after
matching
both the input to G1 AND the output to a matched load....

Goodluck,,

Andy comments:

Well, a piece of wire on the input of a counter is a good way of measuring the freq if you have a strong enough field, but a counter has a threshold effect, and can't be used to infer signal strength other than the difference between "damn strong" and "I can't see it at all".....

Still, enough of a field to measure the 4mhz on a counter is a pretty
strong field.... Not enough to hurt you, but strong nevertheless.

Regarding the skill level of the technician that worked the problem you solved for them..... Well, there's all sorts of people who do this.
Some have the minimal training for installing systems, and some are old ham operators who know a hell of a lot but maybe didn't get a formal education, and are working as cable technicians..... It's good
that you had one that understood the problem when you pointed it out ---- some of them may not have caught on......

Unless you have accurate field strength equip, you can only guess at whether the field exceeds safety levels, but I really doubt, from the info you have given, that it is anywhere close to dangerous levels. More likely it will just annoy the hell out of you if you are trying to

receive a signal anywhere close... and I bet the 4 mhz has harmonics associated that could be annoying also.....

Good luck,

Andy W4OAH

Andy,

The input to the mixer on G1 is the second stage of a DTC. The DTC was
designed to provide the appropriate RP for a 6MHz bandwidth. I then
assumed that G1 will be extremely high impedance compared to the DTC
and therefore would not load it down.

The gain was measured by first measuring the power output of the mixer
and then measuring the power output at the end of the filter.

The manufacturer data for the filter specifies maximum loss of 3dB (they
supply 2 matches filters that connect to form a 4-pole).

The output of the filter was stepped down to 50 Ohms with a C-Tap
impedance transform on the tuned circuit.

The input was matched from 2800 Ohms (Rp of the coil in the mixer tank)
to 800 R using a C-Tap transform also.

I have since constructed a stand alone filter test jig for the filter
only with match on input from 50 Ohms up to 800 and 800 back to 50.

I calibrate the output level with bypass across filter first for
reference level on the spectrum analyzer and then include the filter
in the path.
With this method I measure 4.8 dB loss and the double peaking action has
gone. The 1dB bandwidth was measured at +/- 9kHz.
When I sweep across the required bandwidth (+/-15kHz) I get 2.8dB loss
at the low end and 7.5dB at the high end (relative to the centre peak).
The tuning caps are able to peak the circuit without being turned to max
or min c, so I expect the tuned circuits are resonating ok.

Regards

David

Source record: 11494

Andy,

I realise when I re-read your post that I have not included the loss of the tuned circuit each side of the filter due to Rp of the inductors.

Taking this into account, the max. loss should be around 1.1dB per tuned circuit + 3dB max. for filter = 5.2dB.

I re-measured the response using the digital power meter as this is more accurate than the spectrum analyser relative measurements.

The insertion loss of filter AND tuned circuits was measured at 3.7dB

I then swept the filter and measured the -3dB bandwidth and found this to be -18kHz, + 15.5kHz (very close to the expected +/- 15 kHz).
Next I measured stop band attenuation at +/- 60kHz and measured -47.3 dB on low side and -50.7 dB on high side (manufacture data was for at least 40dB).

I then looked at ripple in the pass band. There was 1 ripple that produces a dip at +9kHz of 1.6dB and a slight peak at +13 kHz of 0.86dB.

This is very close to the 1dB figure mentioned in the datasheet. There was no ripple below Fo.

If I can now get the impedance transformation in my circuit working the same as this then I'm on my way.

I'll leave the output match as-is and if there are issues then it eliminates the output load and just leaves work to do at the mixer end.

This is the first discrete mixer and crystal filter I have constructed. I'm not sure if I am overlooking anything here but to me those figures now look good.

Does this all sound reasonable ?

Thanks heaps

Regards

David

You need to drive it hard for best overload performance.

DGfets were a favorite before DBMs and other high level mixers
or Gilbert cells.

You likely right on. I used 5k as a round number years ago with
success with 3n203s and the BF998 devices have higher GM and
Idss so that would fit with your number.

If you load it low the gain drops but overload and noise performance
is not hurt badly.

The other nasty is most of those filters are more sensitive to
reactive loading than errors is resistive loading. So the scope
probe C (cheap probes can be 7-10pf) can be a real factor
in both meaurement error and circuit loading(capacitive termination).

The fet is a square law mixer so gain and conversion figures are
not the same as if it were straight amplifer. The amplifier form is
two cascaded gain stages and the mixer form is an amplifer with a
series switch, least that model works for me.

Big time! I found that the '141 and friends like to see around 1-2k
impedence level for best gain and at less than 600 ohms it was
pretty poor. Noise figure also improves.

This could be your problem right here -- at 45MHz it's probably not
realistic to expect no loss in the mixer drain circuit. I'd find the Q
of the mixer tank without the filter, and use that to calculate the
effective parallel resistance, as well as the attenuation of the filter.

Well, this might be the best advice I ever got from Usenet. I fought every parameter in the 'HC86 inverter oscillator and lost. The fact that it works great at 14.85MHz and the elegance of using up the extra gates lured me in. The whole thing is very voltage sensitive (around 1Hz/mV at the output of the gate, making it very sensitive to Rs as well). This might be due to the propagation parameters of the gate varying substantially with temperature and voltage.

I built a Colpitts oscillator with a plain old 2N3904 and it hasn't moved by more than a few Hz in the hour it's been on.

Thanks!

Andy writes:

Sounds to me like you are well along the road to being the
world's best receiver designer....

One trick that I used myself when using a scope or spectrum
analyzer to probe volltage to check gain :

I would put about a 0.2 (yes 2/10) of a pf capacitor in series
with my probe, whether highz scope or 50 ohm spect analyzer...
This almost completely "unloads" the circuit when the probe touches
it. There is a great signal loss of course, but since the frequency
is the
same for both input and output measurements, the loss is the same
for each measurement. Relative readings are pretty accurate......
I liked using a spect analyzer cause I could turn the sensitivity
way the hell up, and my measurements would be in db.....

Worked well for me... Maybe others here have some favorite
tricks they can share, too....

I would be pretty confident there is no safety issue.

Looking at
http://www.arrl.org/news/rfsafety/eval/ , the FCC has determined that amateur stations intentionally transmitting just below 4MHz do not need to evaluate human RF exposure until their transmitter power reaches 500 watts. At lower powers, the station simply cannot develop enough RF field to exceed safety standards.

(note that much lower powers trigger safety assessments at higher frequencies; shortwave RF is much less efficiently absorbed in the body, and thus is much safer)

I would be quite confident the RF power in this box is much less than 500 watts. At absolute maximum I could see 5 watts.

Now, the levels necessary to cause interference to shortwave radio reception, on the other hand, are much lower.

IMHO it really isn't necessary to assess the field strength; the cable system is not licensed to transmit at 4MHz, and thus is not allowed to cause interference to SW reception regardless of field.

You're so right about not doing their job for them, and even more
so about them leaking interfering signals. I've got used to being
the first in the area to report problems with the cable: I depend
on the 'Net link being _UP_, and know (from my dayjob) how to do
problem determination and tracing. You get to be the first to report
their problem with something leaking around 4 MHz., and to press the
issue with your city management (if they're city-franchised, as so
many cablecos are) and up the line to the FCC if the cableco and the
franchisor are unresponsive.

Do please keep us posted.

I have looked at used eqpt etc and kits. Most kits are partial kits.
How I wish Heath were still in business :(

Any recommendations for a frequency meter of good accuracy. I dont need high frequency capability - a few MHz is good enough but I need good accuracy.

thanks

Kirk-

Believe it or not, Heath did not go out of business. They just stopped selling Heathkits!

How accurate is accurate? If one part per million is acceptable, many counters will do that. If your requirement is better than that, look for a counter with an oven-controlled crystal oscillator. If that still isn't good enough, you may be able to obtain a Rubidium-controlled oscillator (or GPS-controlled) to use as an external timebase.

If you are willing to spend the money, look at Agilent (HP) and Phillips (Fluke) as sources. If you're looking for a bargain, then there are several HP and Fluke counters that show up on eBay that should meet your needs.

Examples are Fluke's 7220A, 7260A and 7261A. One of these with the high-accuracy option might sell for around $75.

Another good one is the HP 5328, also available with the high-stability option. I think this is the one that shows up in a military configuration that includes the high-stability oscillator as well as a 500 MHz pre-scaler.

3507. How to calculate increase of home wireless router range?

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-07-04 05:57:12 UTC
From: Beverly Erlebacher <bae@cs.toronto.edu>
Message-ID: <2hqacpnj1nwj$.1683sqqzgbbo2$.dlg@40tude.net>
Source record: 11408
Cross-posted to: alt.internet.wireless,rec.radio.amateur.homebrew,rec.radio.amateur.equipment

Can you help me roughly CALCULATE how to increase the range of my home Internet wireless WiFi setup to a shed 300 feet away from my house?

Presently, I can walk about half the way through the wooded area to the shed with my laptop in hand before I lose the connection to the PCMCIA 802.11b,g Linksys card. Basically I need to gain 150 feet in "range".

But how?

At the store, I immediately become confused as I try to compare $30 USD omnidirectional antennas (D-Link ANT24-070) that boost "power" by a claimed 7 db; $50 USD directional corner antennas (Hawking HAI15SC) that claim 15 dbi (whatever a dBi is); and $150 USD 802.11N routers that claim to boost omnidirectional "range" by 4x (Linksys WRT300N).

How does an omnidirectional 7 db or directional 15 dBi boost in "power" equate to range?

Approximately how many decibels of (omnidirectional or directional) power do I really need to boost my WiFi range from about 150 feet to the 300 feet I need?

Looking up what a decibel is (http://en.wikipedia.org/wiki/Decibel#Definition), I calculate the D-Link ANT24-070 omnidirectional antenna gives me about 5 times the power (assuming 7 db = 10^7/10 ~= 5); but does this get me the additional 150 feet of range to my shed?

Spending almost twice as much money on the Hawking HAI15SC directional antenna gets me roughly 30 times the power (assuming 15 db = 10^15/10 ~= 32); but is that enough power to get me the range to my shed?

Indeed, is there some way to add a Hawking 15db antenna on the receiving end to get 1,000 times the power (15 db + 15 db = 30 db = 10^30/10 ~= 1,000); but what would I hook the wire output from this receiving antenna to in the shed (I can't hook it to the pcmcia card, can I)?

Given those db calculations, how do I compare the antenna options with replacing my home 802.11b,g router with the 4X range $150 USD Linksys 802.11n WRT300N router and the required $120 USD Linksys WPC300N PCMCIA card (assuming 6 db = 10^6/10)?Will this three-antenna 802.11n router be forced to drop down to 1X speeds because inside my house my kid's laptops will all be using 802.11b or 802.11g? Or can the router work on both 802.11g to one computer and on 802.11n to the other computer at the same time?

I'm so confused!

All I want is to make a well-informed buying decision to increase my WiFi range reliably to 300 feet to a known point.

Can you help me sort out all these very confusing variable (to me anyway)? I have no training in electrical engineering; but I can google.

Thank you,
Beverly

==========

Very simply - four times the transmitter power (+6 dB) doubles the
range.

Is your receiver sufficiently sensitive? Or is the received signal
below the noise level?

Reg.

Hi Dave,

First thank you for taking the time to help me and anyone who read this.
Second, I'm going to have to go slowly with you so I'll respond one by one.

Third, does your statement that 6 dB of gain equates to 2 times the range
mean that the "square root" of the power difference is my key to
calculating the range?

That is, is this range calculation from dB power roughly true (based on
what you said)?

6 dB = 10^(6/10) ~= 4X the power, where the square root of 4X equals a
doubling the range (assuming an omnidirectional antenna)?

Beverly

> 6 dB = 10^(6/10) ~= 4X the power, where the square root of 4X equals a
> doubling the range (assuming an omnidirectional antenna)?

I'm hoping I can extrapolate from the above statement to calculate the dB gain for the $150 Linksys WRT300N router which claims a 4X range improvement (so I can compare the $50 antenna's effect with that of the 802.11n router).

Following your lead, the power improvement necessary for a 4X range improvement is 4^2 = 16X power gain.

This 16X power gain then equates to about 12 dB (since 12 dB = 10^[12/10] ~= 16X power).

So, is it safe to calculate that the claimed 4X range improvement of the Linksys WRT300N wireless broadband router can be compared to that of a 12 dB gain omnidirectional antenna?

> dBi numbers are approximately 2 dB higher than dBd numbers,
> for the same actual amount of gain.

Hi Dave,

Oh my. I guess the Hawking marketing folks were trying to trick me by
quoting a decibel number that was higher those I compared with.
15 dBi ~= 15 -2 ~= 13 dBd

That makes the $50 USD 15 dBi Hawking HAI15SC Hi_Gain Antenna drop down
from a gain of 32X power to only 20X power which gives me about a 4X range.

13 dBd = 10^(13/10) power ~= 20x power

Assuming the square of the power is the range, I get 4X range.
20^(1/2) ~= 4X range

Assuming my reliable range is 100 feet, that equates to 400 feet of range.
100 feet * 4 = 400 feet range

Interestingly, for comparison purposes, that is the SAME RANGE that the
much more expensive Linksys (Cisco) WRT300N router claims.

Do these calculations make sense?

> range, all else being equal (which it often isn't).
>
> 6 dB of additional gain is four times the delivered power at a given
> distance, or twice the range for the same amount of power.

So that I may compare the different options available at the store to me
for increasing my range, are these simplified calculations below correct?

a. 3 dBd additional gain = 10^(3/10) ~= 2x the delivered power
b. 2x power = 2^(1/2) effective range ~= 1.4X the range

b. 6 dBd additional gain = 10^(6/10) ~= 4x the delivered power
b. 4x power = 4^(1/2) effective range ~= 2X the range

Can someone let me know if these calculations are correct because that
helps me equate the different antennas and routers to the one measure I
desire, which is effective range in the area of 400 feet.

May I ask WHERE that 6 dBd of gain is coming from?

Is it ONLY from the "better" antenna?

If that additional 6 dBd is coming from a "better" antenna, then why didn't
they put that better antenna on my router in the first place?

Since the antenna isn't "powerered", there is no external amplifier .... so
I am a bit confused as to WHERE that power is coming from?

Can you unconfusify me here?

Hmm. At first, I thought you were pulling my leg; but a simple google for
more details gave me more homemade WiFi antenna reading than I can handle
in a month. Whew. Here, for others to share, are the Yagi pringles can
antennas (aka cantenna) which purport to "refocus" the WiFi signal from my
router in my house to my shed 300 feet away.

http://en.wikipedia.org/wiki/Cantenna
http://www.oreillynet.com/cs/weblog/view/wlg/448
http://www.seattlewireless.net/index.cgi/PringlesCantenna
http://www.wi-fiplanet.com/reviews/article.php/3401501
http://www.turnpoint.net/wireless/has.html
http://www.binarywolf.com/249/pringles_cantenna.htm
http://verma.sfsu.edu/users/wireless/pringles.php
http://www.seattlewireless.net/index.cgi/CookieCantenna
http://webserver.computoredge.com/editorial/2339/cover.htm
http://www.signonsandiego.com/news/computing/personaltech/20050613-9999-lz1b13canned.html
http://www.overclock.net/faqs/17669-how-make-pringles-can-signal-booster.html
http://www.g4tv.com/screensavers/features/40546/Pringles_Can_WiFi_Antenna.html
http://www.netscum.com/~clapp/wireless.html
http://www.flickr.com/photos/binarywolf/sets/837698/
http://linuxathome.com/files_images/cantenna.pdf

Given that there are two fundamental design styles:
a) Parabola
b) Tube

Do folks here recommend the pringles cantenna or the pie tin antenna for my
2-antenna router 802.11b,g directional application where I need to also
feed the computers within the house in addition to the shed 300 feet away?

If it does all that, you just have to choose USB, LSB or AM by chosing
sum, difference or magnitude of the IQ output.

Hi Rï¿½gï¿½r,

After reading all the articles posted, I now understand that:

a) The pringles can is hip; but it's the worst performer
http://www.oreillynet.com/cs/weblog/view/wlg/448
(it's not even metal foil lined and it's too small in diameter)

b) The coffee cantenna is more effective than the pringles cantenna
http://www.oreillynet.com/cs/user/view/wlg/1124

c) The dish antenna is the simplest of all and almost as good
http://www.freeantennas.com/projects/template
http://www.freeantennas.com/projects/template2/index.html

I also see, as Rod Speed so kindly noted, that the give and take is that we
lose range in some directions in favor of range in the desired direction.
Fair enough.

My one question is a practical one.

Why are there two antennas on my router anyway? Is one transmit and the
other receive? Or are they both transmit and receive?

Given I have TWO omnidirectional antennas on my wireless router, if I put
the parabolic dish antenna on one to direct it to my shed, does that allow
the OTHER antenna to radiate around the house to handle the other computers
roving around the house?

>
> But how?
==========
Having followed today's postings on this topic , I see that there is a wooded area between your house and shed, hence there seems to be no free line of sight between the house and the shed.
That's why it is difficult to calculate/predict the Gain you need to penetrate the wooded area with a 2.4 GHz signal.

If you wish to use the laptop inside the shed at a fixed location it MIGHT be good enough if you install (for example)a corner reflector yagi (High Gain)antenna at both the house AND the shed. However then your laptop needs a plug-in PCMCIA WiFi tansceiver with a connection for an external antenna.
One of such units is the Make: Buffalo - Air Station Turbo G ,High Power -unit which also has a built-in antenna.
Note : The coaxial cable between the 2 devices and their associated antenna should be limited to only a few metres because of the high frequency being 2.4GHz

Communication here is 2 way . Your laptop might receive the (antenna amplified) signal from your router located in the house ,but that does not mean the router will receive the signal from the laptop without additional facilities at the laptop.

Again , because of the probably partly obstructed path (wooded area) it is difficult making any sensible calculations.

If you aren't afraid of picking up a soldering iron, it is pretty cheap and easy to build a counter. Counters count -- really --, so precision is completely dependent on how long you are willing to wait. 1 second = 1 Hz, 10 seconds = 0.1 Hz. Counters up to about 60 MHz can be built for under $15. (Well, OK, if your junk box isn't very good, and you don't have other projects, shipping for the parts will probably double or triple the cost.) Accuracy is dependent on a crystal, so if you want to get under something like 0.01% you are probably going to have to add an oven to the typical designs you will find on the web. For "a few MHZ", construction is very non-critical. Take a look at OM3CPH's designs for a starting place.

YES - exactly.

I have been able to go laptop to laptop almost a mile with normal PCMCIA cards, using patch antennas. (Well - normal cards modified to bring out the signal to the antenna.) These antennas can be astonishingly directional. Indeed, at 2.4 MHz, it is pretty easy to get antennas with amazing amounts of gain. This translates into VERY CAREFUL aiming of the antenna. Also keep in mind that at 2.4 GHz, RG-58 ain't gonna cut it. Most of what you put in to one end of any normal coax will be sucked up by the coax and won't make it out the other end. You need to use cable appropriate to the frequency.

With a wooded area, not only is it very difficult to calculate, but tiny differences in the positioning of the two ends is going to make a huge difference, as is summer to winter. Even a windy day is going to change things.

Because of the small size, it can be pretty simple to build a yagi for wireless. Yagis won' t have the gain of some of the other types of antennas, but at the same time, they won't be nearly as critical.

Depending on your situation, you may find a directional antenna a better choice than more power. Lots of people driving by like to "borrow" your wireless, and I personally don't like the idea of strangers roaming my LAN, even if they aren't typical crackers. (Seems to me that salesmen are the most common intruders. They have learned that they can find a wireless connection almost anywhere). I find getting coverage into the back yard, while NOT getting coverage well into the street is a bit of a challenge. Yes, I use encryption and MAC filtering, but I'd still rather not have lots of wardrivers trying to break in.

It's not that easy Ben.....

The I-Q demodulator in this chip doesn't include the required 90 deg audio phase shift network. That's usually one of the toughest parts of any phasing-type detector. Also, the LO phase balance is specified as 1.2 deg and the amplitude balance is specified as 0.2 dB. These imbalances would combine to give an opposite sidenabd rejection of less than 40 dB, maybe 35 dB. Not too good by modern standards.

Furthermore, the detector circuits only work at IF frequencies, not RF frequencies. This implies that the internal mixer would have to be used in a downconversion mode, resulting in a requirement for an image-reject bandpass filter at the mixer input and some measure of bandpass filtering at the mixer output.

On top of all this, the LO noise floor is only -100 dBc/Hz, which would probably cause pretty bad reciprocal mixing under crowded band conditions.

All things considered, I think that by the time one made this chip do what it has to do for SSB/AM, one would be better off starting from scratch with more conventional components.

There are restrictions on the RADIATED power, transmitter output power, etc of unlicensed 2.4gHz transmitters, such as WiFi. You should check them out. They vary from country to country.

If you have a ham license, then you can use 2.4gHz for data transmission, but then you are restricted in transmission mode, encryption and data content.

For example, the infamous Pringles can antenna was developed in the U.S. by an FBI agent in the course of an investigation. It's use as a WiFi transmission antenna is illegal in many places. The well pubicised long distance link in Egypt was illegal.

Here in Israel we are limited to 100mW EIRP for civilian useage, except for ham satellite operations which are limited to 25w.

BTW, there are limitations in the U.S. too, I just don't know them.

Geoff.

OK, I found it. It's http://www.arrl.org/qexfiles/LMSProg.zip

(Also, more good stuff to check at http://www.arrl.org/files/)

The zip is very short - 51k, but it contains the program and some auxilary files. The program ran instantly on my Win98 computer. The VB DLL was already installed in \windows\system from previous downloads.

Jack, this looks very interesting and easy to do. Thanks for posting the url.

Andy writes:

While I agree with everything MAC wrote, I think a point is being
missed.
A Quadrature detector is normally used only for FM demodulation. It
accomplishes this by limiting the signal and applying it to one port
of a 90deg detector. If the limited signal is shifted 90 degrees
(narrow
band), the quad detector will detect FM... If the limited signal is
shifted
ZERO degrees, the quad detector will detect AM, and in a much more
linear way than a diode type detector......

With CW, there would be no signal to zero beat with, and no audio
note would be formed.... Exactly the same with SSB....all the output
would be "DC"...

Mac's explanation is correct for an IQ detector... In this case a
local
signal EQUAL to the suppressed carrier of the SSB signal has to
be supplied..... I don't know how a local carrier can be synchronized
to
a SSB carrier that, if done really well, doesn't exist......

In Homodyne receivers, it is easy, since the transmit signal can be

the LO signal..... Otherwise, it has to be "guessed" at..... With
really
really really stable local oscillators, the guess can be really close,
and
the difference will creat an error that is so small it doesn't
matter... But,
since you don't know the incident phase of the received signal, you
have to do both I and Q and shift the IF by 90 degrees and sum (or
difference, depending whether you want USB or LSB) the outputs of
the two channels...... For SSB detection, the RF port is NOT shifted,
the LO port is both 0 and 90 degrees, and the IF port (I and Q) are
shifted 90 and combined........

It is a hell of a lot easier to "approximate" the LO, and shift it
manually
until Donald Duck starts sounding human.... In older SSB rigs, this was

called a "clarifier" control..... It isn't necessary in many modern systems
with really really really good TCXOs and stuff....

Just my two cents worth.... If anyone disagrees, I'd be happy to learn from them where my explanation is wrong..... but I warn you, it ain't far wrong.... cause it worked for me for many many years in designing receivers for both commercial and military products ...:>)))))

Yes.

but (from Analog Devices):
"...Applications of the AD607 include narrowband systems with a high
first IF (21.4 MHz to 300 MHz) and a second IF at 10.7 MHz, 455 kHz, or
450 kHz. These include Dual Conversion IS136, GSM, TETRA, and MSAT
Receivers; and Single or Dual Conversion VHF and HF AM, SSB, CW, or QPSK
Receivers... "

But :-) I did not find any SSB application :-(So I need an example.

Just my two cents worth.... If anyone disagrees, I'd be happy to
> learn from them where my explanation is wrong..... but I warn you,
> it ain't far wrong.... cause it worked for me for many many years
> in designing receivers for both commercial and military products
> ...:>)))))

Andy Thanks for your cents, rather dollars.

PS there is internal quadrature pll in ad607.

Hi Peter Pan,

Oh my! Is "wireless" daisy chaining workable? Is it that easy?

I did not think I could just daisy chain multiple routers! Are you sure?
(My shed has no power but I think I could run an extension cord into it if
that would make things workable.)

Would I just set the second Linksys router (which, amazingly, has it's own
wikipedia entry at http://en.wikipedia.org/wiki/WRT54G) in the shed on the
same channel (SSID=12, name = default) as the first router in the house?

That is, could I put one linksys WRT54G in the house (perhaps with one
antenna replaced with a 7 dBd higher-gain directional antenna); and then
put the other Linksys WRT54G in the shed 300 feet away (perhaps with one of
it's antennas replaced with a similar 7 dBd directional antenna)?

Or, is it best to hardwire with cat5 the first router downstairs in the
house to the second router, say upstairs in the attic window pointing the
antenna toward the shed? I didn't even know that two routers could be daisy
chained. That might solve my dilemma.

Can someone confirm that two routers could be daisy chained either by wire
cat5 cable or by wireless signals as long as they use the same SSID channel
and network name? That solution seems to easy to be true ...

Wow. I've never "modified" a router before but that is interesting that one can increase the $75 Linksys WRT54G router (http://en.wikipedia.org/wiki/WRT54G) RF output from 28 millwatts up to 251 milliwatts (http://tinyurl.com/lpk7w).

Being true to the original intent of this thread, how do I CALCULATE what that does to my range?

Is this 9 dBd calculation of the modification roughly correct?
a) Power gain = Power2/Power1 = 251/28 milliwatts = 9x power gain
b) Range gain = sqrt(Power gain) = sqrt(9) = 3X range gain
c) Range = original range * range gain = 100 feet * 3 = 300 feet

Hi Highland Ham,

I see there are multiple solutions. Probably on the end of my list is
adding a wire to the laptop because then it wouldn't be wireless. Still,
it's an intriguing idea (I never knew laptops could have fixed antenna's

connected to them by wire).

If I do use two antennas, does that "add" the gain?

a) Antenna 1 transmits with a directional gain of, say 7 dBd
b) Antenna 2 receives with a directional gain of, say 7 dBd
c) Does that get me a 14 dBd overall gain?

> If your goal is to increase your range then add an extender
> (hams would prefer to call them repeaters).

Oh my. The seemingly perfect option.

I had come across the concept of wireless "repeaters" in my initial googling before I went to the store, e.g., in this Microsoft "how to increase range" article http://www.microsoft.com/athome/moredone/wirelesstips.mspx and in this "Extending WLAN Range" article http://www.wi-fiplanet.com/tutorials/article.php/1571601

The repeater most often recommended was the "Linksys Wireless-G Range Expander WRE54G".

However, I can't find that 802.11b,g WiFi repeater (aka range expander or extender) anywhere in the local stores. The salesperson who sold me the $300 USD 802.11n router and PCMCIA card combination said they didn't work so they dropped it.

This solution seems to be the most elegant of all (but someone else suggested just using a second router).

Can someone unconfusify the situation?

Is placing a repeater (on the same SSID) in the shed really the same as adding a second router instead?

Hi David,

Interesting this speed difference. I'm worried about RANGE and all of a sudden other factors come into play! Thank you for enlightening me. I know more now than I ever did from you wonderful guys!

As I noted to someone else just now, I DID try to find the "Linksys Wireless-G Range Expander WRE54G" WiFi repeater in the local stores but they did not exist in any of the three stores I checked.

Also, some of the articles talk about an "access point" (http://www.wi-fiplanet.com/tutorials/article.php/1571601).

Can someone tell me what part of my setup I would call the "access point"?

Hi Stephen,
I'm confused about this "access point" thing.

Is that the same as a "router"?

Is it as simple as buying a second router (routers are familiar to me) and
just hooking that second router to the first router by cable and that would
extend my range by the distance of the cable connecting the two routers?

This is a key confusion point for me!

And wireless channels, as well. Some of the channels are outside the U.S.
ham bands. Since this is an amateur radio newsgroup, I made the (possibly
rash) assumption that OP was aware of these limitations. For amateurs in
the U.S., the main issue is encryption. Few of us can afford to get
anywhere near the power limits at these frequencies!

Andy responds;

Ok.. I admit that I didn't go find the AD607 and study it before
replying
to Mac... However,,, I'll bet you a dollar that the fellow who wrote
the
app note that Mac refers to has a hell of a lot less experience than
either Mac or myself..... not that I would expect a young app note
writer to overstate the applications of his product (big damn grin
)...
The AD606 really makes a great tie-tac if you glue an alligator clip
to it, tho I've never actually seen one for sale... :>)))))))

if the gilbert cell, or single ended long tailed pair multiplier
used as a
quad detector allows external coupling to the ports, it can be used as
a BFO for CW or SSB,..., HOWEVER, having a limiting stage in the
linear path of such a device is NOT a great idea.... Sure, it can be
made
to work, but..... well, heck... I've built a LOT of things that were
really
bad ideas, and I try not to duplicate them again, or tell others about

them.... especially in app notes that I've made input to......
I've seen the MC3372 used as an SSB receiver in either Ham Radio
or some such.... and I never seriously considered doing it myself since
the limitations were so obvious....

An 811A can be used a a product detector also, but the
manufacturers
don't advertise it as such,..... because it is a REALLY BAD idea....
If a fellow wants a simple CW/SSB receiver, a much better idea is to
use something like an NE602..... I've done that, for a home project ,
and
it works OK,..... but certainly not something I'd try to produce as a
receiver for Bendix, Texas Instruments, or Raytheon..... There's a
limit
to how far one should stretch an application.....

Thanks Mac, for your input. I bet we agree on almost
everything.....

Andy,

You really should go and read the data sheet on the AD607.

1) It's a linear component with no limiter stages
2) It has an "I-Q" detector, not a "quadrature detector".

Comparing it to the MC3372, or any other FM detector chip, is as far off
base as comparing it to an 811.

However, having said all that, I think we would agree that there are better
and simpler solutions for amateur SSB and AM applications.

An access point is a device with an ethernet port on one side and a wifi port on the other. In technical terms it would be called a "bridge". It "bridges" two seperate network segments, although in this case they use different topologies (100Base-T and WiFi).

> Is that the same as a "router"?

The usual WiFi router consists of a four port ethernet hub (LAN ports), a seperate single ethernet port (WAN port) and a WiFi access point. It is set up to "route" between the single (aka WAN) port and the other two ports, the LAN and WiFi. Most of what it does for routing is NAT (network address translation) and some sort of IP tunneling.

If you ignore the WAN port and just use the LAN ports, you have a four port hub and an access point.

> Is it as simple as buying a second router (routers are familiar to me) and
> just hooking that second router to the first router by cable and that would
> extend my range by the distance of the cable connecting the two routers?

Yes. Just make sure to use the LAN ports. It would be best to use different channels. Most WiFi clients are smart enough to use the channel that is the strongest if they have access points on more than one with the same SSID.

Make sure to use encryption. Encryption is NOT to keep your data safe, nothing can do that. If someone is intent on accessing your network, WEP encryption will not keep them out.

What it is for is to convince the guy driving down the street looking for an open network to send out SPAM, or "share" kiddie porn, to drive on. Unfortunately, most users don't even change the SSID of their network, let alone set an encryption key.

Having tuned in late, if you want to have an open network, look up PublicIP. It's a "live cd" that runs on a PII or better (x86) computer and provides all the functions you need to offer a secure and safe open network.

That's a shame. Here in Israel we are limited to 100mw EIRP, which severly limits the transmit antenna. There is NO limitation on the receive antenna.

The 33k/150 were chosen to get CMOS compatible output. The circuit will
oscillate with much higher values for each.

The two 100p might be slightly too high for the 18p crystal I'm using,
but I didn't tune those carefully because I want to pull the crystal
slightly, and in my actual circuit the grounded leg of the crystal is
actually in series with a variable capacitance to tune the VCXO.

A receive antenna has no EIRP, it doesnt radiate any real power.

AndyS napisa?(a):
I bet we agree on almost
> everything.....

Generally Yesss

But (always but) :-))))

I never used mc3372 as ssb rx, but permanently used mc3362.
But... - mc3362 id dual conversion RX and i used second mixer as a
product detector leaving original fm detector "out of business".
I am not good in quadrature detectors, and i don't know what
(technically) is mixer (rather mixers) in ad607. I have only 1 piece of
IC, it's surface mount, and I'm afraid, that if I use it in my test
board I will have nothing to use in my receiver.

Of course I used ne602/612 in many constructions, (genetally trx with
switched BFO/VFO - Atlas idea), but this time the idea is to use as low
elements as possible to build a rx with "quite good" performance.

Serious (other or better ;-)) idea in my wokshop is TGX with1st mixer
on fst3125 with companion of ad600 IF ampli (only one) in typical
application (application note with simple ad590 and one transistor AGC)
- not this "high performance agc system from Exp. Methods...

On the other hand - it is the best way in our HAM life - to use parts in
the way, which was not inntended by "creators". It's a part of our love
to ham radio :-)

Nice and inspirating talk Andy. Greetings from Poland

Hi Ben, Thanks. What is the nominal setting of the cap in series with the crystal? 18pf or so?

Do you have any info on the crystal, such as make and model?

Or any idea what the series resistance might be?

Would you like me to post the results to my web site?

Regards,

Mike Monett

The Columbus, Ohio QRP Club did a group build of an LC meter based on the project in "Everyday Practical Electronics" magazine, February 2004 issue. The URL is http://www.qsl.net/cqrp/projects.html.

For some reason, the link to the members' meters is no longer working.

This meter has slightly better capacitance range specs than the AADE meter, as reported by ARRL on the website awhile ago.

If you are interested, I am building this meter, and I can give you some additional information about it. Please email me directly, removing the ** from my email address.

The "varicap" is actually a red LED, which G0UPL characterized as about
30p down to about 20p over 0..5V:

http://www.hanssummers.com/radio/varicap/index.htm

> Do you have any info on the crystal, such as make and model?

It's a Digi-Key X231-ND, mfg p/n ECS-250-18-4-F. Digikey has the
datasheet. I think the ESR was 40 ohms.

> Would you like me to post the results to my web site?

Sure.

Andy writes:

God how I hate surface mount.... It used to be that I could send
away for a freebee, or buy a chip from Digikey, and get normal,
civilized, 1/10 lead spacing pins that I could use in a socket, or
use the pins as tie point for "dead bug".....
I could build a circuit up as fast as I could go and the connecting
of the parts together was an insignificant part of the process...

NOW, for the last several years, all freebees I have received have
been surface mount. I have to work under a magnifying glass, with
a special thingy for my soldering iron, and use small pieces of copper
wire strand that I get out of lamp cord to expand the chip to the point
where I can actually attach resistors and capacitors.... it takes more
time
to expand the surface mount than to build the rest of the circuit... As
a
result, I lose enthusiasm a lot.....

I have a few things that I have done with surface mount, but I long
for the good old days..... Fortunately, I have about 30 years of
accumulated freebees that I haven't gotten around to using, and can
usually come up with a way to build something.... However, the miracle
chips (as I call them) that Analog Dev, and others, are coming out with
are just too damn much trouble for me.......

If anyone here has some SIMPLE solutions for the surface mount thing,
that does NOT include making a custom PC board, I'd like to learn
about them.....

I second the HP 5328 -- you can also get very good results with the HP 3586 measurement receiverif you only need to go to some 10's of MHz. These often show up with stabilized crystal ovens.

I have also used an HP5334 and much prefer the HP5328.

Hi Ben,

I found the ECS spec at http://www.ecsxtal.com/search.html

The numbers are:

Shunt capacitance C0 7pf

drive level 0.5mW maximum

max esr 30 ohms

Using these values plus the standard beta value supplied with the SPICE model for the 2N3904, the oscillator runs pretty good. It doesn't clip, and puts out a good signal to drive CMOS.

But the crystal dissipation is about 5.88 milliwatts, or about 11.7 times the max spec value.

Since this is so far above spec, there's not much reason to go further and spend the time to post the waveforms.

3560. Garage hamshacks? Here is my garage "secret lab"...

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-07-05 06:03:43 UTC
From: Straydog <asd@panix.com>
Message-ID: <Pine.NEB.4.63.0607050142060.14331@panix2.panix.com>
Source record: 11311

(FYI/FWIW)

Recently there were a lot of comments on using a garage as a hamshack.

My problem was not the hamshack, but where to build my "retro" tube-based ham gear (HF) and my garage gets cold in the winter (30s F and below at worst) and too hot (90 F) and humid in the summer. So I decided to build a "cubicle" out of plywood (5/8" for me, leftover from a hurricane passby that I used to cover our most expensive windows). So I had these pieces of 4' x 6' that I put together to make a cubicle 6' high, 4' wide, and 8' deep, and put in a 18" wide "bench" (made out of a piece of lam pine about 6-7' long. This gets the drill noises, the soldering smoke, and all the little metal shavings, drillings, file dust, etc., out of the house and away from our rugs and somewhere where I don't have to be constantly cleaning it up.

For the winter, a standard electric space heater easily warms up the inside in less than 1/2 hour, and in the summer, a small A/C cools it off in minutes. The A/C vents the hot air into the garage but it does not seem to warm up the garage much beyond what it warms up in normal hot weather (I mention this because the warranty says it will be voided if you do this, but I'm only doing this once a week all, or as much of the day, as possible). On the A/C, many will collect significant amounts of condensed water and then excess will drip out on the "outside" but I've found in such a small cubicle that running the A/C for many hours does not cause significant amounts of water to accumulate and perhaps this is due to the small volume of the cubicle and once it is dehumidified, not much new water vapor enters over a whole afternoon or more. I mention this because I was concerned about having a constant drip of water onto the garage floor. This has not happened yet (not a drop has come out).

For anyone who wants to see images of this cubicle (for building stuff), they along with images of some of my homebrew gear, kludge-ugly-all-from-the-junkbox, can be found at:

http://www.panix.com/~asd

Just look for the links to the "secret lab" and click on them.

FYI/FWIW: The rest of that index page lists the done projects and the in progress projects (as well as pics of prior rigs of mostly commercial gear I've had during most of my ham career).

Hi all,

Any EN 300-220 European standard guru out there ?

I have some difficulties to deduce the maximum phase noise profile of a transmitter from this standard in the case of a very narrow bandwidth transmitter (say 10KHz bandwidth, operating in a non-standard VHF frequency band) :

- Standard gives a limitation of the transmitted power in the adjacent channels (10 W integrated over each adjacent channel). Fine
- Standard gives a limitation for the spurious emissions (-36/-54dBm under 1GHz with 100KHz spectrum analyzer bandwidth depending on the frequency). Fine.

But what is the maximum noise or side modulation levels say 2, 3 or 10 channels away from the carrier ? My first assumption was that the "spurious" specification was applicable, but with a 100KHz resolution bandwidth I would be measuring the carrier power if I do the measurement even 5 channels away from the carrier...

Any help welcome...

Friendly yours,
Robert

It'll tune to 465Khz no problem.
But if not, use an aluminium slug instead of the ferrite one. This will
have the opposite effect to the original one. ie - more aluminium
inside the transformer = Higher operating frequency

POE! POE! POE! (Power over ethernet). Put the access point at the antenna,
run a cat-5 cable (4 twisted pairs) to it. Four get used for the network
connection, 4 get used for DC.

Not only does it work well, but CAT-5 wire is cheap, 2.4gHz low loss coax
is not.

Geoff.

I'm going to make a guess on this. At pretty low f, absorbtion starts to
go down. I know they communicate with submarines with RF carriers around
12-14 kc because ocean water is almost transparent. Only when absorption
of RF gets high then there are "bioeffects" (mostly thermal, but there is
controversy about non-thermal effects). Others here might be able to be
more specific for that range 14 khz to 300 khz.

Small Wonder Labs sells the Freq Mite for $20.00 - if you build it and put it in an Altoids tin, you'd have a nice small portable freq counter.

With all that...

AD607 does NOT have a "quadrature detector". It has an "I & Q demodulator".
BIG difference. You must read the datasheet and app notes to use it
correctly. It is capable of demudulating many types of modulation. [typo

You need to be more specific. There are "frequency counters" (common) that
are different from "frequency meters" (older equipment and more rare).
How many is a "few MHz."
What is "good accuracy" ?
What are you measuring ?
What is your price range ?

If a Heath frequency counter will do, then any frequency counter available
will probably do.

Elenco has small counters that start at $150
http://www.elenco.com/

Similar small units:
http://www.optoelectronics.com/cub.htm

http://www.apogeekits.com/frequency_counter.htm

Andy comments:
Using the 1992 ARRL handbook regarding the proposed ANSI standard,
Figure 4, page 36-4, I get the following at 80 khz..

Efield : 600 V/m or 100mw/ sq cm (these are the same levels)

Hfield: 1000 watt/ sq cm (this is a power density form of H
field)
This is 163 amps/meter

These are for both controlled and uncontrolled environments, and
are DIFFERENT levels.. In other words, the allowable safe H field
is a LOT more powerful than the safe E field .

These are really damn big numbers and I don't think you should worry
much about them unless you play golf in the rain.......... :>)))))

Andy in Eureka, Texas W4OAH\

(The chart is small, and my glasses are thick, so I apologize for
any lack of precision....)

Do a search on the phasing method of SSB reception, then the "Weaver" method. Either of those should get you a block diagram showing what to do with the I and Q outputs.

3574. Re: Garage hamshacks? Here is my garage "secret lab"...

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-07-06 00:57:22 UTC
From: Kirk <kirkmcloren@yahoo.com>
Message-ID: <1152147442.917448.256100@m73g2000cwd.googlegroups.com>
Source record: 11325

A thermometer is the only safe way to know how much it is heating the
garage.
It is not how many days a week you do this that is dangerous - it is
the peak temperature. Pressure in the system is a function of condenser
temperature and the manufacturer often doesnt design beyond 110F as
tubing isnt free (heat exchanger) nor fan horsepower(plus most weather
is below 110 except in a few places). Excessive pressure increases the
run current on the pump (compressor) which is cooled by refrigerant
flow. As temperature rises on the air to the condenser heat in the
system also increases due to higher run current so it stacks up fast.
The higher EER units have more heat exchanger and are a bit more
tolerant.

3575. Matching SA602 mixer to SA605

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-07-06 10:13:07 UTC
From: David <websales@orbitcoms.com>
Message-ID: <Tm5rg.412$tE5.236@news-server.bigpond.net.au>
Source record: 11326

I am looking for a reasonably efficient method of coupling a 602 mixer output to a 605 input at 45MHz.

I have tried a tuned circuit with coupling caps and did not get good results. Both the 602 and 605 are working fine independently. (I tested the 605 with a match up from 50 Ohms to 1k5).

I am wanting a receiver with around 10dB signal to noise ratio at -115 to -118dBm.
Signal frequency is 151 MHz.
1st IF is 45MHz, 2nd IF is 455kHz(+/-15 kHz bandwidth).
The input filter has a bandwidth of 6MHz.
The image should not be an issue as it is way down at 60MHz.

I don't want to loose much gain between the 602 and 605 (about 3-5dB would be acceptable).

Thanks in advance

Regards

David

David,

"...did not get good results" is a very fuzzy description of the problem you encountered. Can you be more specific?. Is the problem a sensitivity problem? Why do you think it's an interstage coupling issue?

You don't say whether you're coupling from the '602's mixer output into the '605's mixer input, or from the '602's mixer output into the '605's IF input. In the former case, the 605's input resistance is in the 4.5K range while in the latter case the input resistances is about 1.5K. The '602 output resistance is also in the 1.5K range. In either case the output/input resistances are already close enough to be within a few dB of optimum with just a DC blocking cap for coupling (assuming the interface is resonant). I don't know why you weren't successful in just resonating the output of the '602 and capacitively coupling into the '605 with a large coupling cap. Can you tell us what values you used?

Without analyzing this in detail, I'd say that if your interstage coupling is resonant and tight (large coupling cap), then your sensitivity performance will probably be limited by the noise figures of the two mixers in cascade (assuming that the tuned input circuit isn't real lossy).

Most likely it is a 2SK2746 MOSFET. The datasheet might give you some
clues:

http://www.semicon.toshiba.co.jp/docget.jsp?pid=2SK2746&lang=en&type=datasheet

>Hello group --- What is replacement for Toshiba K2746 transistor. John

It's almost certainly a 2SK2746: "Silicon N-channel MOS type field effect transistor for high speed, high current switching, DC-DC converter and motor drive applications" according to the info at www.datasheetarchive.com. Maximum ratings are 800 volts, 7 amps DC, 21 amps pulse, 30 volts on the gate, 150 watts dissipation.

http://www.mark5.co.uk/ seems to have some in stock, but the prices seem high. DigiKey carries the 2SK2746 but it looks as if they don't care to sell them in quantities less than 3000 pieces, special-order only.

It looks to me as if an International Rectifier IRFPE50 might quality as a substitute (same voltage rating, same threshold-voltage range, slightly better Rds(on), Id, and Pd ratings) - DigiKey has these in stock for under $7 each.

One site suggests the SSM09N70F as a substitute.

I never tried to use this chip as an SSB detector, but I did design an AM sync detector a couple of years back. I remember that I had to limit the input level to around 30uV when used in the fashion, but it wasn't bad for that purpose.

3583. Confused with BF998

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-07-07 08:29:54 UTC
From: David <websales@orbitcoms.com>
Message-ID: <6Yorg.900$tE5.231@news-server.bigpond.net.au>
Source record: 11335

I am going around in circles attempting to understand the datsheet for the BF998 Dual Gate FET.

From what I can gather, with Vcc = 8V and 4V on G1 and ID of 10mA, at 150 MHz
Input appears to be 1700 Ohms with 2.1pF par
Output appears to be 1250 Ohms with 1pF par

(I thought Fets had hundreds of K ohm input impedance - or is this only at low Freq ?)

The typology I have is.

L/C tuned circuit to G1
100K+100K providing 4V to G2 (with 100n Bypass cap close to gate)
The source has 100R with 100n Par to ground.
The Drain has the Inductor of the tuned circuit to Vcc (and bypassing on Vcc side as well as 47R series resistor for additional decoupling).

The tuning cap goes from Drain to ground.

I have about 250mV on the source (only 2.5mV bias current).

How do I obtain 10mA drain current ? Or are they only referring to AC current ?

Would someone mind please giving me a bit of overview of these devices.

Thanks in advance

Regards

David

MOSFETs have a very high input resistance, but the actual input
impedance at high frequencies is a lot lower.

Leon

3585. Re: Confused with BF998

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-07-07 11:54:51 UTC
From: David <websales@orbitcoms.com>
Message-ID: <fYrrg.1008$tE5.721@news-server.bigpond.net.au>
Source record: 11337

Opps, I see my finger trouble.

The input was stated as Y = 0.06mS +j 2mS . This would be almost 17K in
parallel with 2.1pF NOT 1k7

The output was Y = 0.08mS +j 0.8mS. This should be 12.5k in par with
just under 1pF. Not 1250 Ohms

OK, I am getting some understanding I just need some gaps filled in now.

I see that when the recommended gate voltage is applied to G2 that Rs is
adjusted for the required current (say 10mA for lowest noise figure).

So, If I put 4V of G2, grounded G1 via and RFC and RFC on drain to Vcc
then placed a 100R in the source, I could adjust the 100R till 10mA
flowed to set the bias point.

I suppose then you would match the 12k drain impedance to a tank
circuit. Or place the tank circuit as the load.

Is the gain of the amp just related to Gm and the load impedance on the
drain.
So that if the DC bias was set for specific VDS and VGS then there would
be a specific transfer admittance that would produce a current through
the load. With RFC there would be max. gain or gain could be fixed by
specific load less than this?

Thanks

Regards

David

At DC and low frequencies the inputs are effectively open circuits
(very high R) with a small C across it. As frequency increases the
package(leads and all) and that small C combine to reflect
a decreasing impedence.

Also those numbers are for best noise performance as RF amplifier.

I'd usually use lower value resistors like 10k to ground and 47k to V+
for G2. G1 is returned to ground through tuned circuit L.

I use 12V on the drain.

As RF amp or mixer? As RF the bias on G1 and G2 must be correct.
For Mixer that would likely not be the case.

3588. 813 power amplifier - design safety advice/tips?

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-07-07 18:04:10 UTC
From: dave <foda01@epix.net>
Message-ID: <umxrg.322$Pa.38929@news1.epix.net>
Source record: 11339

Hello,

I am putting together a push-pull power amplifier based on the 813 power tube. It will have about 1.5 to 1.7kV on the plates and put out at least 260 watts into a 9k load.

I am not new to high voltage tube circuits, but this is the first time I will be working with potentials this high (above 1kV). I am aware of all of the usual safety precautions, but I was hoping to get some specific tips for putting together a design like this from some people who work with these sort of voltages, hence the posting here.

For the plate supply, I have a Hammond power transformer laying around here rated at 1000-0-1000 volts @ 200mA. From the ap notes on the 813, I am know that the tubes will idle at about 50 mA and peak at about 305 mA. Would this Hammond be ok for this type of use? I dont *think* I would be drawing 300 mils anywhere near continuously, but you never know. This amp will be part of a bass guitar amplifier for live performance use.

I want to use solid state rectifiers and in studying some older ARRL handbooks, they tell you to use equalizing resistors and small caps across series-strung diodes to get up to the peak inverse voltage you need. However I have seen a newer part in Mouser, made by Rectron, rated at 800mA and 8kV PIV. Would something like this be all I would need (four in a bridge configuration)? I would think it would be easier than making all of those strings up from individual diodes. Or is there a better way?

I want to use a choke-input supply and I happen to have a large old filter reactor made by Chicago Transformer rated at 20H @ 250mA, with a test voltage of 6kV.

As for filter caps, I guess the cheapest way to go is to string together series electrolytics with balancing resistors.

Also I have seen a lot of supplies use soft-start relays in the primary - would you think this would be necessary in this application? I am looking to get about 1.6kV out of this supply.

So basically you have a 2000vac secondary feeding a bridge of high voltage rectifier diodes, then a 20H choke, and then a string of 'lytics. How much capacitance would be sufficient to elliminate the hum in the plates? I know that with push-pull and beam power tubes you can probably stang higher ripple in the plates but is there a good ballpark figure?

Also since the 813 is directly-heated, would it be ok to have one 10v, 10A filament transformer to light them both or would it be best to have two separate ones to allow for hum balance -pots or for some other reason?

I also will have to make a screen supply for 750 volts at 45mA max. Would this have to be a regulated supply?

I had planned on ordering some Belden 18awg high voltage test lead wire rated to 10kV for all of the plate supply wiring. Would this be ok, or is there a better wire for this application?

By the way I am having Heyboer custom wind an output transformer for this thing. It was fairly expensive (around $200) so I want to protect it as best as possible - fuses, etc - any ideas there?

Basically I'm looking for any ideas that might not be at first obvious, in terms of providing safety to me, the operator, or the most exensive components -

Any and all ideas/tips/etc. most welcome

Dave

3589. What is a wire antenna's impedance?

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-07-07 19:29:54 UTC
From: jo9s8as@yahoo.com
Message-ID: <1152300593.974477.241010@35g2000cwc.googlegroups.com>
Source record: 11340

I searched all over the Internet and many books but just could not find a formula or rough number of a wire antenna's impedance (not dipole or anything else, just a simple, plain wire). I need this number to match my small transmitter's final stage output, about 10mW, at 450MHz. The final stage's transistor has fT of 6GHz, and is not unconditionally stable at 450MHz. So I need to match it using Smith Chart. I know those portion of work. But I just don't know the wire's impedance's range, say, is it in the 50-80 ohms or in the 500-600 ohms range or even 1000-2000 ohms? Right now I do not guess this number right, and my transmitter seems always oscillating at a wrong frequency. So take an example, if I use a wire antenna, say, 22 AWG, spools of solid, and the length=wavelength/4, what is its approximate impedance? Thanks.

Have you tried "Antennas for All Applications" by Kraus
(http://www.amazon.com/gp/product/0072321032/sr=8-1/qid=1152301289/ref=pd_bbs_1/002-7389034-2641652?ie=UTF8)?
It has plenty of plots of input impedance for various antennas. Any
university library will have some edition of Kraus' book; it's been around for
decades.

I'm about 99% certain the ARRL handbook has plenty of antenna impledance plots
as well.

> But I just don't know the wire's impedance's range,
> say, is it in the 50-80 ohms or in the 500-600 ohms range or even
> 1000-2000 ohms?

For most antennas at least in the ballpark of resonance, you'll be in the
30-300 ohm range. Real antennas often have tens to hundreds of ohms of
reactance as well, though.

> So take an
> example, if I use a wire antenna, say, 22 AWG, spools of solid, and the
> length=wavelength/4, what is its approximate impedance?

In the ballpark of 72 ohms assuming it's a dipole (lambda/4 on either side);
if you're operating lambda/4 above a ground plane, it'll be roughly half that.

I believe the demo (free!) version of EZNEC will answer your
questions. Google for it. One of the most critical aspects of any
antenna is where it is with respect to ground.

As the other posters pointed out, it depends on it's length, where it is above what kind of ground, and how it is fed. It will be influenced by stuff around it like aluminum siding, fences, trees, and all sorts of things. Some of the influences aren't minor, unless they are all wavelengths away.

If you have an end-fed quarter wave, which I suspect is what you are describing, then it needs to be fed against something, most likely ground. In that case, it will be about thirty ohms at resonance, plus the resistance of your ground, which could be substantial. That assumes "free space", of course, which isn't bloody likely. More likely you are relatively close to a less than perfect ground, so the impedance could be almost anything. Even in a perfect world, with pefect ground, the impedance varies with height above ground.

It isn't like there is some simple answer that is being kept secret. It is a complex question, with lots of variables. As one poster pointed out, the best answer short of measuring it, is to model it with something like EZNEC.

You indicated your objective was to come up with some sort of impedance transformation from a rig you are building to this antenna. Given the opportunity for significant reactance, I would suggest you locate someone locally with an antenna analyzer and measure it! An SWR bridge won't tell you enough to design the matching circuit; there will be reactance, and a 2:1 SWR says IF it is all resistive, maybe it is 25 ohms, maybe 100. You have no reason to suspect either and likely there is some reactance so probably it is neither.

So go measure it!

..

Very dependent on length, distance from groundplane, diameter
and skin resistance of the material.

The best answer is knowing it's only a wire and no defined information
more than that is: 42!

OK MAc,
All I know is the I & Q modulator and demodulators are the industry
standard in commercial radios like the ones my company designs. I hrae that
you can get anything you want. I'm too far away from the current designs to
know anything specific.
A Google resulted in this , but it doesn't appear to be a complete how-to.
http://www.merrimacind.com/rfmw/02intro_modulators.pdf

Perhaps someone can explain how to "I & Q" to get SSB, etc.

Good luck 73, K9DCI

The simplest way I found - is to use an ear in companion of brain - :-)
I am serious - look for "binaural DC receiver" (Exp. Methods in RF
design) when one can see, that "i" is and "q" are simply amplified and
feed headphones. Thats all. But then we have still problem with lsb/usb.

Thanks for link.

3597. Re: 813 power amplifier - design safety advice/tips?

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-07-08 00:15:47 UTC
From: Highland Ham <abcgm0csz.kn6whxyz@dsl.pipex.com>
Message-ID: <KaidnWfXDb63ZDPZnZ2dnUVZ8qidnZ2d@pipex.net>
Source record: 11348

1) The power supply transformer has a centre tap ,hence is meant to be a 1000 V -200 mA ,hence 200Watts supply device. When you would use it as a 2000V-AC device the primary winding and or the 'iron' will highly likely be inadequate to produce 400W of power.
So the transformer will NOT be capable of supplying 1600* 0.305 equals 490 Watts. You will need a transformer which can supply at least 2.5 times the power you get from your available transformer .

2)Depending on the transformer voltage available say 1300 V the max rectified DC voltage (due to the capacitor(s) will be 1.4* 1300 equals 1820 V ,hence the PIV of a bridge diode string would have to be at least twice as high ,with a safety factor ,say 4000 if not 5000 V
It depends of the type of diode you use but if it is one with a PIV of 1000V you'll need 4 to 5 diodes in a bridge arm string.
Modern avalanche diodes are known not needing parallel capacitors or resistors . The Recton diodes are highly likely a molded set of lower PIV diodes . You could find out how many diodes are in series by applying a low forward bias dc current and measure the voltage across the module At approx 0.7 V across each diode you then can determine the number of diodes in the module. You obviously can also use a string of 1N4007 1 Ampere diodes each having a PIV of 1000 V

3)The choke designed for 250 mA might be OK ,although is somewhat marginal .Its resistance will cause a drop of the DC voltage hence in order to get the required final DC supply voltage at max load the transformer voltage has to be adequate . It also means that you have to determine how much 'voltage sagging' is permissable.

4) If you use a string of electrolytic filter capacitors you need a sufficient number to suit the rectifier bridge output voltage multiplied by 1.4 and should apply a decent safety factor. Assuming you use identical caps ,the overall capacitance is of course the value of 1 divided by the number of caps .
You have to pay much attention to the equalising resistors taking into account both their voltage and power rating .
A well know RF Power Amplifier designer ,AG6K , recommends MOF =Metal Oxide Film
resistors , although often one sees high power wire wound resistors on a ceramic core being used.

5) You also need to decide in which operating Class the valves will have to work in view of the acceptable distortion level of the amplifier. Class A would be best but a waste of energy. In the intended push pull configuration Class B would be OK.

6) The screen voltage of both valves will have to be stabilised

7) You also have to ensure that the valves are being cooled ,by means of one or more small fans. A good method is to have an airtight under-chassis pressurised by a small centrifugal fan and the valve sockets fitted just below the chassis (on stand-offs)such that the air flows along the valve bases and up. It might also be useful to apply anode connectors with cooling fins.

8) If amplifier enclosure has a hatch giving access to High Voltage carrying components it is essential that when the hatch is opened a microswitch opens ,cutting all external power if left on. Normally of course power should be cut (power supply plug pulled) and then ,only after a few minutes, the hatch should be opened, because of retention of charge by the filter capacitors for some time (depending on the value of the voltage equalising resistors).

These are just a few of many aspects to consider when building a valve power amplifier.

Havent looked much at the AD part but... it's a mixer
(actually two of them).

See articles by KK7B and Breed. Basically the I (inphase)
and Q (quadrature) mixers are fed with RF at 90 degree relation to
each other. The resulting output is then put through a 90degree
delay (use 3rd order allpass networks for that) and sum or difference
the result and you have a phasing SSB/CW reciever. If you can keep
the phase and amplitude errors better than 1% (easy with modern parts)
you get 40+ db of alternate sideband suppression. All the work is
done in the audio range so Opamps are good for this or DSP. Look up

R2, MIniR2, or R2pro for more details. Summary is if you delay the Q path by 90degrees and add the result there will be a frequency(s) where the results add to each other and as you get past zero beat they will subtract from each other.

One note on alternate sideband suppression, 40db is pretty good sounding, 50db is achieveable and 60db is tough.

I've built a SSB transceiver using the KK7B miniR2 design and opposite sideband suppression is 45db or so and it sounds far better on the air than the typical minimal RX with a 4 crystal ladder filter. I run a MiniR2 and T2 (phasing TX) on 6m with a 6W output. Gets rave reviews for clean signal and it's very good TRX for DX.

Source record: 11350

Unfortunately, there's no such thing as a "simple, plain, wire". Any current you put into the wire will force an equal current into the "ground" connection. If, for example, you just plug a wire into the center conductor of your transmitter's output connector, a current will flow out of the connector along the outside transmitter's chassis. This current will equal the current into your wire. So the radio, along with the path to the Earth, becomes the other half of a very asymmetrical dipole. You can't avoid this, except by making the return current flow where you want, for example into the other half of a regular symmetrical dipole.

So to simply answer your question, if the wire is very close to a quarter wavelength and connected as I've said, the resistance can be anything from 10 or a few tens of ohms (if it's close to the chassis) to a thousand or more ohms (if the path to the Earth is particular lengths). The reactance can easily be plus or minus a few hundred ohms.

That's why you don't find a simple formula. If you did find one, it would be wrong and useless.

If the XFmer is 1000-0-1000 with rectifiers (Full wave configuration)
you can count on around 1550V at 200ma or ~310W DC power.
You can load that higher if the peak to average is in the 300W range.
If you use a full wave bridge you can get twice the voltage and run
the same 200ma at ~2800-3000V for 600W.

The nasty with a 3000V supply is everything has to stand at least
10KV (allow for transients at least 2x or 3x the supply). Also 813s
may arc over at this high a voltage. (use 4-400s!).

The caveat is for sound amps and music overbuilding is a good thing.
Serious overbuilding is sometime required for commercial (stage)
use. Nothing worse than an amp smoking when the perfromer was.
Most I knew back when used multiple smaller amps rather than one
BIG one all driven from one head.

Either way works. follow the recommeded add xxx percent over rating to prevent the smoke from escaping.

>I want to use a choke-input supply and I happen to have a large old filter
>reactor made by Chicago Transformer rated at 20H @ 250mA, with a test
>voltage of 6kV.

Ok to 250ma and the power xfmer is 200ma so it's a winner to those limits. You can go past that but then heating and peak to average considerations apply (and shorter life is possible).

>As for filter caps, I guess the cheapest way to go is to string together
>series electrolytics with balancing resistors.

It is the way to go. Lots of them! Don't forget all those resistors are eating up that limited 200ma, they are needed but it emphasizes the limited transformer your using.

>Also I have seen a lot of supplies use soft-start relays in the primary -
>would you think this would be necessary in this application? I am looking
>to get about 1.6kV out of this supply.

Yes, saves popping mains fuses from power on surges and also is easier on the HV components.

FYI: the filliments on the 813s must be up to temp before DC plate or screen power is applied.

>So basically you have a 2000vac secondary feeding a bridge of high voltage

>capacitance would be sufficient to elliminate the hum in the plates? I know
>that with push-pull and beam power tubes you can probably stang higher
>ripple in the plates but is there a good ballpark figure?

Enough to keep the ripple at full load less than 1%. Start around 60-100uf.

See caveat for ~3000V on plates!

Pushpull will help balance out ripple.

>Also since the 813 is directly-heated, would it be ok to have one 10v, 10A
>filament transformer to light them both or would it be best to have two
>separate ones to allow for hum balance -pots or for some other reason?

One of adaquate current rating with a 50 ohm pot with the wiper to ground for balance will do. That 50ohm pot is a high power resistor. The alternate is a 10V center tapped or two 5V transformers.

>I also will have to make a screen supply for 750 volts at 45mA max. Would
>this have to be a regulated supply?

Absolutely. Likely you will need another transformer, rectifier and filter for that voltage as you only have a 200ma transformer for the plates so why waste some of it on the screens. Also the screen supply must not be applied before the plate voltage.

Not needed if you use 811 or other power triode.

>I had planned on ordering some Belden 18awg high voltage test lead wire
>rated to 10kV for all of the plate supply wiring. Would this be ok, or is
>there a better wire for this application?

Consider that the environment is not only HV but also HOT. Make sure
the wire (and all your parts) can stand heat too.

>By the way I am having Heyboer custom wind an output transformer for this
>thing. It was fairly expensive (around $200) so I want to protect it as
>best as possible - fuses, etc - any ideas there?

Fuses should abound. Minimally, mains input, and DC to plate
transformer.

>Basically I'm looking for any ideas that might not be at first obvious, in
>terms of providing safety to me, the operator, or the most exensive
>components -

ENCLOSE everything with HV on it. Finger proof it. and provide
interlocks. Consider cooling as well.

>Any and all ideas/tips/etc. most welcome

Reminder 2 813s with only filliments lit are pumping out some 100W
of heat! (10V at 5A).

The tubes should be biased between class AB1 and B for minimum
distortion. that means at idle you likely standing 20-50ma per tube
(another 50-150W of heat!).

You also need a -V (0-100V) negative to bias the tubes.
Another small transformer as trivial current is needed
mostly for bias pot and bleeders.

Mechanical construction is important as with all that iron
(transformers) it's going to be heavy. I mean wheels on this
beast are a must.

You also need a driver and that will have it's own power needs
though only a few watts need be developed. The low level amps
need to be kept far from the power transformers or it will HUM.

That sounds like a pole mounted UPS. I used to design CATV systems
and headends.

=======================================

It is not clear what impedance you are talking about.

If you are asking what is the Zo impedance of an antenna conductor
considered as a transmission line, then it is -

Zo = 60 * (Ln(4 * L / D) - 1) ohms,

where L is length of the conductir, D is its diameter, and Ln is
natural logarithms to base e. L and D are in the same measurement
units.

You have mentioned Smith Charts in your query. Zo is usually in the
region of 300 to 600 ohms for wire antennas. The above formula is
approximate and is good enough for ordinary purposes.

Reg.

Have you got the audio output transformer for this beastie? - if not, get a price before you start - you might reconsider the project.

It is going to be physicaly big, very heavy, and fragile - 813 filaments dont like being knocked around in the back of a truck (and you will need a truck or SUV to move it) so if its intended to go on the road, it might be more trouble than its worth.

But, so saying that, ----- nice lunatic fringe project - worth doing, just for the hell of it, and ignore practical realities......

Andrew VK3BFA.

I spent several years in my teens using my dad's Heathkit SB-102 rig out in the garage in Fort Worth. Yes, it does get hot around here during the summer, make no mistake about it. I'm a night owl by nature, and I can't count how many times I worked DX until the sun came up.

Pros and Cons:

* Keep the garage door open, and open the back door as well to let air flow through. Cheap, but effective only during the day. At night, june bugs and other critters are attracted by the interior lights and will make life miserable for you. (I'll never forget one on-air conversation when a june bug flew right down my shirt. "WHAAAAUUUGH!!!") These days, unfortunately, it's not wise to leave your garage door open unattended because some *@#$ might come in and steal all of your power tools. (Bitter experience.) Or worse.

* Our garage had a VERY good wall-mounted air conditioner. It worked beautifully, even during the long, crushingly hot summer of 1980. In fact, it saved my parents' bacon when the house's main A/C unit failed and it took a couple of days to get it fixed. Mom & Dad just backed the car out of the garage, plopped down a mattress, turned on the wall-mounted A/C, and slept in cool comfort. [I'm sure Dad woke up each morning wondering, "What did she do to the bedroom now?"] Nice backup to have. I could work 40 meters all night long without worrying about the heat or the bugs.

* The garage also served as a nice workshop, complete with parts cabinets, two workbenches, and lots of tools. Easy to try out new RF circuits quickly.

I like the tornado-shelter idea. It's smaller and easier to keep cool. Also easier to secure valuable equipiment.

Thanks to all who responded - some very good points to ponder...

I think I should spring for a different plate transformer, since I don't want to be running this one too marginally. Also, I suppose I could do away with the choke and still get under 1% ripple. That would definitely lighten up the weight. The Hammond # 720 is rated 625-0-625 V at 300mA CCS and 500mA ICAS, so I guess that would be adequate.

I am using a free program called PSU Designer II to calculate the power supply values and outputs. With the Hammond #720 and a 40uF/47ohm/40uF C-R-C filter after the diode bridge, I should get about 1760VDC at 50mA and about 1660VDC at 300mA.

I was also thinking of using three toggle switches across the front panel for filaments, plates, and screens, arranged so as to reflect the order in which to apply the power. I suppose some sort of relay or other device could be used to make sure the screens never got power before or in place of the plates. It is a good idea about the interlocks on the chassis too - I know nobody else will be using this amp besides me but still always a good idea to design in the safety. Also it won't be toured around as I play in basement bands most of the time so it probably won't see too much road use. It's more of a crazy way to generate 300 watts rather than go with the ordinary 'three pairs of KT88 's' route.

thanks again sincerely for all the input!

Dave

==========
Instead of having 3 separate switches ,go for a single manual switch , a
sequential timer or separate timers and have 3 front panel lights for
filaments ,anodes and screen voltages. With 3 separate switches you
might operate these in the wrong sequence. With the 3 lights to come on
sequentially you quickly can detect any possible sequential switching
problems.

> Actually, when properly matched, it radiates half the received power.

How do you get that?
If the receiver input impedance is matched to the antenna, all the
received power is absorbed. There is no reflection. There is no radiation.

If the receiver matching is for optimal noise figure, there may be
some reflection and reradiation, but there's nothing pinning it to
be half the received power.

Don

John is correct. A receiving antenna, when matched, reradiates half the power it receives. An impinging field induces current in the antenna. This causes radiation, just like the current in a transmitting antenna. As it turns out, when the antenna is matched, the amount of power radiated equals the amount of power delivered to the load, and that's the best you can do. If you'd like a more in-depth and mathematical explanation, you can find it in any antenna text, often discussed as "scattering".

If a receiving antenna did absorb all the impinging power, it would be a lot easier to make a shield or a stealth aircraft.

Yes but that ISNT ANY REAL POWER in the EIRP restriction sense.

It's real power, but that power all comes from the impinging field; it's not contributing any new power. So you're right that the EIRP restriction doesn't apply. The receive antenna reduces the amount of power in the field by the amount delivered to the antenna's termination, plus any losses along the way. The intent of the EIRP restriction is to limit the amount of field strength added by a transmitter.

Never ever could bullshit its way out of a wet paper bag.

> Rod, I suggest you LEARN something from your intellectual and
> technical betters BEFORE you show the world your ignorance.

Never ever could bullshit its way out of a wet paper bag.

While your original was technically correct, its completely
irrelevant to what was actually being discussed, WHETHER
THE RECEIVE ANTENNA EVER RADIATES ENOUGH TO
BE RELEVANT TO THE EIRP RESTRICTION.

And that is what was being discussed when John made such a
spectacular fool of himself mindlessly rabbiting on about what
is no news to anyone with a clue about receiving antennas.

Duh. So John was mindlessly rabbiting on about a complete
irrelevancy WHEN THE EIRP RESTRICTION WAS BEING DISCUSSED.

You have always been, and always will be, completely and utterly irrelevant.

What you may or may not be inclined to believe in spades.

Anyone with a clue considers the facts, not the style stuff, fuckwit.

> Make of that what you will,

I flush it where it belongs.

> but my suggestion is to counter with rational
> argument backed up by references and facts,

Dont need 'references' on that basic fact that even
when the receiving antenna does reradiate about
half of what it receives, THAT IS COMPLETELY
IRRELEVANT TO THE LEGISLATED ERIP LEVEL.

> rather than insults and obscenities.

I suggest you take your stupid suggestion
and shove it up your arse, where it belongs.

Maybe to some extent, it's a matter of nit-picking over what
"received power" means. You can think of an antenna as having an
effective aperture size over which it captures all the energy
crossing that cross-sectional area. To me it's logical to think
of "received power" as the power that actually gets scooped
up and delivered.

Effective aperture increases with antenna gain. Obviously something like a dipole has a relatively small effective aperture. But the effective aperture of a high-gain horn antenna for instance, will approach its actual physical cross-sectional area.

For instance, look at Figure 13 in this pdf.
http://www.coe.montana.edu/ee/rwolff/EE548/EE548-S06/UWB/Intro_UWBAntennas.pdf

What type of package is it in? The Toshiba data-sheet says
it is a gual-gate GaAs FET in a surface mount package.

Your description sounds more like a TO-50 pill or X type package.
Most Japanese dual-gate FETs in pill packages use the same
pinout as the BF981. The long lead is probably the drain,
although I have seen a few that had a long lead for G1.

3628. Re: What is a wire antenna's impedance?

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-07-09 16:37:56 UTC
From: jo9s8as@yahoo.com
Message-ID: <1152463076.490252.133390@b28g2000cwb.googlegroups.com>
Source record: 11379

Thanks, everyone. But you guys still made things complicated. I said it is just wire antenna, only for a very small output power, 10mW. In order to eliminate the confusion or misunderstanding, let me put some pictures to illustrate:

(1) This transmitter, 10mW, at 450MHz, wire length(lambda/4 for 450MHz)=16cm. What is the wire antenna's impedance?
http://www.charto.info/antq1.jpg
(2) This transmitter, 10MW, at 450MHz, Rod Extendable Antenna is extended exactly as 16cm(lambda/4 for 450MHz). What is its antenna's impedance?
http://www.charto.info/antq2.jpg

Given that such specific conditions are as shown in the pictures, is it still difficult to tell, even for a rough number within a range such as 50 to 80 ohms, or 500-800 ohms?

jo9s8as@yahoo.com wrote:
> Thanks, everyone. But you guys still made things complicated.

No, they didn't. Antennas themselves are complicated. Formulas exist only for specific well-defined environments, none of which fits your configuration close enough to be meaningful.

> I said it
> is just wire antenna, only for a very small output power, 10mW.

Output power has nothing to do with antenna impedance.

> 50 to 80 ohms, or 500-800 ohms?

Yes, it is. And, whatever number you are given will not necessarily be correct from one time to another. The impedance will change if you pick up the radio or the camera. The impedance will change if you change position to be near another object.

Suppose you are told that the impedance will be 20-j35? What will you do about it? Since you feel that the expert advice you received simply complicated the issue, one can only assume that you do not have the knowledge to cope with an answer.

Go to your local ham club and find somebody with an antenna analyzer. Put a quarter-wave wire into the connector and wander around while recording the maximum resistance and reactance. You can see it change all over the place. No, it doesn't go from zero to infinity. The impedance will be different from that when the antenna is installed on your actual object.

Here is a number. Do with it what you will.... Z ~ 35-j35. If you don't like this number, get EZNEC and model your own antenna. Or, get your own analyzer and measure your wire. Be sure to include hand and body capacitance in your

model. Also be sure to model your tripod, soil conditions, nearby trees, the object enclosure, etc.

Good luck.

John

Best get your seems machinery seen to then.

Its a fact that even when a receiving antenna does radiate back
half of what it recieves, THAT IS NOT RELEVANT TO WHAT WAS
BEING DISCUSSED, THE LEGISLATED EIRP LEVEL ALLOWED.

Not a shred of opinion involved what so ever.

Look at this part of the thread...

[John said:]
If the receiver matching is for optimal noise figure, there may be
some reflection and reradiation, but there's nothing pinning it to
be half the received power.

[Roy said:]
John is correct.

[Rod said:]
Nope.

[Roy said:]
A receiving antenna, when matched, reradiates half the power it
receives.

[Rod said:]
Yes but that ISNT ANY REAL POWER in the EIRP restriction sense.

So John made a factual statment. Roy agreed. Your opinion was to
disagree with the simple factual statment.

Roy added a clarifying statment. You started to go off the hook and
SHOUT because you were fixated on EIRP. When I read it I never saw any

direct implication about EIRP or legalities in the explanation; it was a simple explanation about antennas.

Your *opinion* was involved in deciding you knew the exact intent of the posting and that it had implications in the EIRP thing, just because that is the interpretation that passed through your mind.

Ok, I'm done here. Not sure why I took the time for this one last post.

Not about that particular para of John's. I was saying that John was
not correct on the original point about whatever the receiving anntenna
radiates BEING RELEVANT TO THE LEGISLATED EIRP LEVEL.

No opinion there, just fact.

> [Roy said:]

> So John made a factual statment. Roy agreed.

It wasnt relevant to what was actually being discussed,
WHETHER WHATEVER THE RECEIVING ANTENNA

RADIATES HAS ANYTHING TO DO WITH THE LEGISLATED
EIRP WAS ACTUALLY BEING DISCUSSED.

> Your opinion was to disagree with the simple factual statment.

It wasnt an opinion, it was a statement of fact that that
comment John made WAS NOT RELEVANT TO THE
LEGISLATED EIRP LEVEL THAT WAS BEING DISCUSSED.

> Roy added a clarifying statment. You started to go off the
> hook and SHOUT because you were fixated on EIRP.

The legislated EIRP level WAS WHAT WAS BEING DISCUSSED
WHEN JOHN MADE SUCH A SPECTACULAR FOOL OF HIMSELF
RABBITING ON ABOUT WHAT THE RECIEVING ANTENNA RADIATES.

> When I read it I never saw any direct implication about EIRP or legalities
> in the explanation; it was a simple explanation about antennas.

Pity it was a comment made WHEN THE LEGISLATED EIRP LEVEL WAS
BEING DISCUSSED WITH REFERENCE TO THE RECEIVING ANTENNA.

> Your *opinion* was involved in deciding you knew the exact intent of the posting

Wrong again. It is a FACT that John's comment had no
relevance what so ever to what was being discussed,
whether the receiving antenna has any relevance what
so ever to the legislated EIRP level. It doesnt.

> and that it had implications in the EIRP thing, just because
> that is the interpretation that passed through your mind.

Nothing to do with my mind, it was what was being discussed.

> Ok, I'm done here. Not sure why I took the time for this one last post.

Yeah, you just made a VERY spectacular fool of yourself, yet again.

I'm not so sure. I couldn't find any specific references to this
effect in several books I skimmed. Same with internet searches. If
true, then the concept of converting solar power in an orbital
satellite, converting it to microwaves, beaming it down to an antenna
array in the middle of the desert, and converting it back to
electricity, isn't going to work if the array re-radiates half the
power. That's going to ruin quite a few nifty science fiction stories
and innovative business plans.

I also note that the common microwave path analysis calculations don't take re-radiation into account. For example, if I start with an EIRP of perhaps XX dBm from a transmit antenna, -YY dB of path loss, and ZZ dB receive antenna gain, the power delivered to the receiver (ignoring coax losses) is calculated at (XX - YY + ZZ) dBm without any mention of the -3dB that would need to be subtracted if half the receive power is re-radiated from the rx antenna. It would seem that the common formula and web forms for link calculations are -3dB off.

I trust your judgement in such matters and you have far more expience than me, but something seems wrong or I'm missing something. Can you point me to any books or refernences? I just skimmed Chapter 2 (Fundamentals of Antennas) in "Antenna Engineering Handbook" by Jasik (1961) and found no obvious mention of this effect.

Antennas For All Applications by John D. Kraus and Ronald J. Marhefka
Third Edition
Page 746, Paragraph 21-15

"Prec=(Rr/(Ra+Rr))Pa

where

Rr=receiver impedance, ohms
Ra=antenna radiation resistance, ohms

For a perfect match, Rr=Ra, so that

Prec=(Rr/(Rr+Rr))Pa=0.5Pa (W)

and the receiver gets 1/2 the power collected by the antenna. The other half
is reradiated."

Also see "TV and Other Receiving Antennas" by Arnold B. Bailey published in
1950 by Rider Publishing. Beginning on page 235 near the bottom:

"In radio receiving antennas the predominant resistance is, strangely
enough, largely due to the fact that no electrons can move on the antenna
surface *without also sending radio energy back out into space*. So here we
have the paradox of a receiving antenna, having the prime function of
collecting or extracting energy from space, but unable to do so *without
itself returning radio energy of like kind* into space. The amount which it
returns is one-half of the total that it extracts under properly matched
conditions. In a good installation, with the antenna properly connected to
its receiver load, the receiving antenna will be able to *deliver to its

load one-half of the energy* it extracts from the oncoming radio wave but, by necessity, *must return the other half to free space*. A receiving antenna, then, is itself a *new source* of radiation. This is not so surprising, since *any* reflecting surface, as we have seen, establishes a new source of radiation"

(Note: The emphasis in the book was italics)

Scroggie's "Foundations of Wireless", the book I cut my teeth on (and
my father before me...) mentions this in the chapter on Radiation and
Aerials where he describes the reratiation as a fact of great
importance in recieving aerial design.

I think however Rod's final remark is perhaps the most telling - if an
antenna really did absorb all the energy landing on it, there would be
highly curious side effects.

3640. Computer alternative to Smith Chart?

I haven't used a Smith Chart in over 30 years, and to say the least, I'm a bit rusty. I'm thinking there must be computer programs that can do the calculations with values you just plugs in. Any recommendations? I'm specifically interested in finding the impedances of antenna whips much shorter than 1/4 wave.

Absolutely.

You could get a pretty good idea of the impedance of the antenna with a carefully constructed model and a modeling program if the device case is metal and you assume that the device won't be anywhere near a person or other conducting object. If it is, the person or object has to be included in the model. There's no nifty and simple equation or rule of thumb which will tell you.

You don't seem to understand that the "antenna" is only part of the antenna whose impedance you're asking. The other part is the box and whatever it's attached to or whomever is holding it. The "antenna"'s impact on the impedance is no greater or less than the impact of the rest of the real antenna, i.e., the box and what it's connected to.

If the box is plastic, then internal wires and boards are the other part of the real antenna, and have a major impact on the impedance.

I'm curious. How do you use a Smith chart to find an antenna impedance?

There certainly are programs specifically designed to find such things
as antenna impedances. The free EZNEC demo program from http://eznec.com
would be adequate and ideal for your purpose.

OK, that make sense. Thanks much.

So, why is NASA and other disreputable organizations still pushing
beaming solar power down to earth via microwaves?
| http://en.wikipedia.org/wiki/Solar_power_satellite
| http://en.wikipedia.org/wiki/Microwave_power_transmission
| http://science.nasa.gov/headlines/y2001/ast23mar_1.htm
| http://www.spacefuture.com/archive/conceptual_study_of_a_solar_power_satellite_sps_2000.
shtml
| http://www.msfc.nasa.gov/news/news/releases/1999/99-096.html
| http://www.ieee-virtual-museum.org/exhibit/exhibit.php?id=159265&lid=1&seq=13
No mention in any of these that half the delivered power gets
re-radiated. If the receive array were anywhere as directional as the
xmit array, then it would cook the satellite. The re-radiated power
has to go somewhere. Oh, maybe because it's a government project the
number don't need to be correct?

I'll spare you the usual anal joke about rectenna.

Also, why is there no -3dB added loss on the receive end of wireless
path calculation? From what I can deduce from the path calcs, the
receive antenna delivers all the power to the coax cable and then to
the receiver. Where's the half power (-3dB) loss?

I'm still (half way) mystified.

>Also see "TV and Other Receiving Antennas" by Arnold B. Bailey published in
>1950 by Rider Publishing. Beginning on page 235 near the bottom:

Argh. That was published 2 years after I was born.

>"In radio receiving antennas the predominant resistance is, strangely
>enough, largely due to the fact that no electrons can move on the antenna
>surface *without also sending radio energy back out into space*.

Resistance? Unless he's thinking of ohmic resistance, most antennas
don't have any resistance. (Well, a rhombic has a 300-400 ohm load,
but that's not what we're discussing). If the signal gets
re-radiated, without any loss, there can't be any dissipative elements
in the system. What resistance?

There's a nice impedance spiral in Kraus: "Antennas".

For Linux (and probably other Unix-type systems running X) there's a
nice free program called Linsmith.

I could add more references to the ones already mentioned, but you should be able to find it in most antenna texts. Look in the index under aperture and scattering cross section. When dealing with path loss calculations, the effective aperture is used, and this has the reradiation already accounted for. In fact, the reradiated power has its own descriptive unit, the scattering aperture. A good and brief description of these can be found in Kraus' _Antennas_, p. 29ff, and many other texts.

You're right that the antennas used to receive beamed power will catch only half of it at best. But many, many business plans have been developed and billions in stock sold for schemes which are much less plausible. For starters, how about the current idea of hydrogen "fuel", "made from water"? (For those not acquainted with the harsh reality of thermodynamics, it takes more energy to extract hydrogen from water than you'll get back when you burn it. Charlatans notwithstanding, there's just flat no way around this little fact.) Then there's SDI. . .

The point of hydrogen is a means of energy storage and transmission, not
power generation. Typically the hydrogen will be released from water by
solar or nuclear power. See:
<http://en.wikipedia.org/wiki/Hydrogen_economy>
<http://auto.howstuffworks.com/hydrogen-economy.htm>

3649. Toroid or molded inductor in low voltage tank?

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-07-10 06:50:58 UTC
From: Ben Jackson <ben@ben.com>
Message-ID: <slrneb3u6i.172.ben@saturn.home.ben.com>
Source record: 11250

In a coupling circuit such as:

```
C1|| C3||
IN>----||----o----o----||--OUT>
|| | | ||
--- C
--- C L1
C2| C
| |
'----'
|
===
GND
```

(see, eg, the "38 Special" NorCal 30m QRP tranceiver sch connecting the NE602 single-ended output to an amplification stage: http://www.amqrp.org/kits/38spcl/)

What is the purpose maximizing the Q of L1 by using, say, a hand-wound toroid vs a molded inductor? Rs of a 1.8uH moulded inductor might be 1.5 ohms vs .1 ohm for 5 inches of 24ga wire. However the expected effect in tank bandwidth doesn't seem to matter compared to the large effect of varying C1 (very narrow for small C1, 5p in the example).

I can see why a homebrewer would prefer to keep a bag of T37-2 and some enamelled wire around, but in a kit such as that, wouldn't a moulded inductor do just as well?

The much lower Q of the molded inductor can result in significantly worse rejection of spurious outputs from the amplifier. I don't know whether that's important for this particular design or not. But a toroid also has other advantages over a solenoidal inductor. A toroid has a much smaller external field, so it can be mounted close to other components including other inductors with minimal mutual coupling. For the same reason, a solenoid's Q can be degraded substantially by proximity to other components or conductors, while a toroid is relatively immune to this problem.

Ben,

Don't confuse the 'unloaded' Q of the part with the 'loaded Q' of the
circuit.

The unloaded Q of the part is a measure of internal resistance in the part
and will mainly affect the loss of the network, not the bandwidth. The
loaded Q of the network is a measure of the external network resistance that
the part is embedded in and will mainly determine the bandwidth.
The ratio of unloaded Q to loaded Q will determine the losses of the network
(higher unloaded Q is better).

In general, high unloaded component Q is 'goodness'.

For real operating systems (anything Unix based -- Linux OSX or a real Unix)
try Linsmith http://jcoppens.com/soft/linsmith/index.en.php

Hi, Bob -

http://zaffora.f2o.org/W9DMK/W9dmk.html has one.

About 3/4 of the way down the page.

It won't help you find antenna impedance unless you plan to measure the Z at the input end of the line and use the tool to get antenna Z. As has been said, you can use EZNEC to model your antenna and get its impedance.

However, a Smith chart can be very useful for matching a thing to another thing.

The one I use (a demo) I got from the University of Applied Sciences in Berne, Switzerland. I like it. However, it appears that it has been removed from the host. If you want it, I can send it to you. It is zipped to 306 kb in size.

Cheers,
John

3657. Re: Computer alternative to Smith Chart?

Newsgroup: rec.radio.amateur.homebrew

Source record: 11258

Andy adds:

I have often used a modified Smith Chart , called an
Impedance/Admittance
chart , to do matching..... If the impedances are not greatly
mismatched,
it is very easy and accurate.... and very very intuitive...

The ones I used have the impedance cordinates in black and the
admittance coordinates in red.....

I found them extremly useful in the design of an automated antenna
tuner
which I designed for a Texas Instruments Marine SSB unit, back in the
late 70s..... You could literally track the impedance transormation
mentally
with series and shunt elements.....

True, but it's such a low level as to normally be considered
insignificant. Unfortunately some take that to mean there is none.

If there were none, a Yagi antenna which used all passive elements
save for the driven element would not work. On receive that driven
element plays an active (pardon the pun) roll.

True, but the ones that use the dynamic encryption can do a reasonably
good job along with a firewall and router. The golden rule is
"Nothing is bullet proof"

One of the locals mentioned doing a bit of "war driving" around town
just for curiosity. About 80 to 90% of the networks heard were
unencrypted AND over half of those _still_used_
the_default_name_and_PW.
I use hard wired Cat5e in a gigabit network as with the amount of
traffic wireless is just too slow even if it is full duplex.

NOTE I only receive the two amateur radio news groups.

For a quick graphic demonstration of what the other posters are pointing out without having to build and measure a physical circuit, try putting this circuit into "RFSim99" (a free program), and select "Use physical model" in the inductor value dialog box. Then change the unloaded Q of the inductor there to see the effects on performance, both loss and filter sharpness (--> rejection of unwanted signals). You'll need to connect "IN" and "OUT" to measurement ports (one of the available components in RFSim99) that you set to appropriate impedances.

Such a simulation doesn't address the effects that Roy mentioned of coupling to external fields and lowering of Q by coupling to external material. On the other hand, though toroid coils have lower coupling to externals, their coupling isn't zero, especially when you use a low-mu core---so be careful how you mount the toroids, too. In a couple minutes, the simulation can give you some insights to get you started and save a lot of time soldering, but expect to ultimately learn even more by actually building and measuring the circuit.

Cheers,
Tom

Thanks, I'd been looking for something like that.

> unloaded Q of the inductor there to see the effects on performance,
> both loss and filter sharpness (--> rejection of unwanted signals).

I see. So the reason that the Q matters so much is not that it affects the filter shape much (in this topology), but that it has a big effect on the amplitude of the (tiny) passband which provides additional separation from the unwanted signals. In this case it looks like raising from Q=50 to 250 gives about 4dB of "wanted" signal without really affecting anything else.

> couple minutes, the simulation can give you some insights to get you
> started and save a lot of time soldering, but expect to ultimately
> learn even more by actually building and measuring the circuit.

I actually have such a circuit built, and I took some measurements today. I'll wind a 1.8uH inductor on a T37-2 tonight and compare.

Thanks to all for the responses.

Still, that's a special case.

I can choose a different special case with a different result.
For a large, high-gain aperture-type antenna such as a big horn or dish,
virtually the received energy orthogonally incident on its cross-section
will be sucked up and absorbed.

Therefore you can't really say that an antenna always radiates at least
half the received power.

Don

Not even in the same universe -- WEP is easily cracked in minutes,
little more than the Emperor's new clothes. Use WPA with a strong
passphrase for any real security.

At least until the antenna starts to melt. :-)

I have a suspicion that many of the "random wire" antennas you see on something like his video transmitter are actually roughly lambda/2 ("end-fed zepps") -- seems to me their impedance wouldn't be as sensitive to the exact positioning relative to the case, his hands, etc., and that the higher impedance is often easier to match to for a low-power transmitter anyway.

There was an article on 1/2 wave whips for handhelds a few months ago in QEX. The author did quite a bit of experimentation, as I recall, and specifically made a hand-held metal box on which to mount the antenna so that his body, hands, etc would be included in his measurements. I remember his comment about how far away from his mouth he held the box and antenna to make his measurements.

But, I don't know how this would compare with a 1/4 wave whip for sensitivities. It is interesting to insert a 1/4 wave whip into an MFJ269, walk around, and watch the readings.

Ok, I wound 20 turns of about 30ga wire on a T30-2 and compared before/
after (each with the trim cap set for peak) and it's about 2.75V p-p
vs 2.0V p-p, or ~3dB. I'll put it on the spectrum analyzer at work
again to make sure the unwanted products are still in the same place,
but it looks like a win for high Q.

Thanks to everyone who replied, it was very educational!

Anyone have any tips for securing fine-wire toroids in
Ugly/Manhattan construction? :)

3673. 2MHz stepup transformer formula ?

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-07-11 05:49:27 UTC
From: Georg Holderied <Georg.Holderied@unibas.ch>
Message-ID: <44b39e24@maser.urz.unibas.ch>
Source record: 11281

I need to build a transformer that transforms the output of a signal
generator (0.5-2 Mhz 0-20Vpp into 50 ohms) into two opposite phases
at 0-250V.

Load is a few picofarads and a short length of shielded cable.

Where can I find formulas for winding such a transformer ?

Is it preferable to build it as an air or on a ferrite core ?

What ferrite material would I use ?

BTW the signal is used for driving multipole ion traps.

I am an electrical engineer but have not much experience with RF.

George

The driven elements should be resonant and connected to a matched
load, while the parasitic elements are off-resonance and not connected
to a matched load, but they are just grounded to the (virtual) boom.

Thus, it is quite natural, that the parasitic elements will reradiate
any energy from the passing field and hopefully the reradiation from
all parasitic elements arrive in correct phase to the driven element,
to form the desired radiation pattern.

Paul

A dab of hot melt glue or RTV. Or a Nylon screw through the middle. Or a couple of holes in the board and a cable tie. The only thing to avoid is laying it down flat on a solid copper plane.

========================
You probably mean 'shame on the users' who haven't got a clue.

By the way it is the same situation here in the north of Scotland .
Driving in Inverness you can freely access WiFi points allover town
,from commercial companies to hotels..........but not at locations where
you would expect it ....like 'Starbuck' and bookshops like 'Borders'
Also in California you have to pay for WiFi access at
Starbuck.........must constitute a increasing part of their
income,considering the number of people with laptops.....usually without
a coffee..

I know ,I know ...life isn't a freebee

This will go on until the Scotish police start doing what the English do. They track traffic at the ISP level looking for "kidde porn". Once they find it, they locate the person sending or receiving the files.

They have no trouble getting a warrant and come in and arrest the owner of the account and confiscate their equipment.

As soon as they do this, "users" will go looking for unencrypted networks and use them, if they don't know I don't know Scotish law, but in most places the owner of the network is responsible for what is done with it.

There was a case in Canada of a man found driving five miles per hour in a residential neighborhood. When the police stopped him, his pants were around his ankles and there was a laptop on his lap.

Canada unlike most places has a law prohibiting using other people's internet connections without permission. Most places don't.

Geoff.

Roy

Excuse my ignorance, but what is the problem with laying a toroid down on a solid copper plane? I thought the magnetic field was contained within the toroid and thus minimised external effects. I have completed a couple of projects recently with some of the inductors like that and didn't notice any real problem. Mind you, I guess they might have performed better if not mounted that way :o)

Folks,

The Flying Pigs Run For The Bacon is Sunday Night! Get ready for some
CW QRP
sprint fun!

To clear up any confusion about the time of the event, the RFTB will
ALWAYS be from:

9-11 Eastern time
8-10 Central time
7-9 Mountain time
6-8 Pacific time

This is year around, regardless of any daylight savings/standard time
changes.

Hope to hear you Sunday Night!

As an Engineer in my eighties with a long association with transmission lines of all sorts I have never used a Smith Chart, in anger, in the whole of my life. I have always used log tables, sliderules, pocket calculators or, more recently, dedicated computer programs.

Use of mathematics gives one a more 'intuitive' insight into how transmission lines work than any chart. But it's a just a matter of opinion and depends on one's basic education.

As useful as they were only at HF, Smith Charts became redundent when the personal computer came in. Old habits die hard!

No, I mean shame on the wireless hardware companies, as I wrote, for
such a gross disservice to their customers -- it shouldn't be necessary
to be an IT expert to use Wi-Fi safely. It should just work properly.
Otherwise it's not ready for the market.

Twofold. One is added capacitance across the windings and secondary
is the proximitry of a conductor to the small field around the wire(s)
that are not in direct contact with the toroid.

Georg,

If you transform a 20VAC signal from a 50 ohm source into a 250VAC signal, the 250VAC output will be at an impedance of about 7,800 ohms (conservation of energy; Po = Pin). At this high impedance you won't be able to drive virtually any length of coax, even open-circuited, as just a few tens of pF of cable capacitance will cause a significant rolloff at 2 MHz. What load impedance do you intend to drive?

BTW, 20Vpp at 50 ohms out of your 'signal generator' is quite a signal - about 1 watt. Is this really the case?

Yes. Many years ago I attended a lecture. The lecturer handed round Smith Charts as a tutorial. We spent 10 minutes on it. But these days I'm well out of practice.

The Smith Chart was only of any use at HF and above. That's what it was invented for. Fine for radio amateurs who only use the HF bands and above. It followed on from previous, more complicated Victorian Age charts to ease calculations involving complex Hyperbolic functions. Very good while it lasted.

Small, dedicated computer programs these days are more accurate and time saving than charts and their 'what-if' operating procedures are much more educational.

But I appreciate the sentimental attachment, indeed affection, many old timers have for the good old Smith Chart. By all means carry on using them.

I think that is the engineer in you speaking!

I find the Smith Chart interesting as a tool. I am more interested in how it works while you are interested in what it is good for!

My desk drawers still contain a couple of slide rules, a polar planimeter, a drafting set and a Kurta Calculator. In spite of being surrounded by an assortment of computers, I keep a good battery in my HP Calculator and I remain fond of nomograms.

The Smith Chart is a tool. I cannot possibly have too many tools...

Of course I have archived the programs at g4fgq as well...

We could quit teaching Calculus as well, Computers make quick work of graphic solutions!

John, you've weighed me up fairly well.
On the other hand I see much beauty in Mathematics. And program source coding is the labour of love and a Work of Art. But Maths is a much neglected subject in our Western schools and universities these days. Even teachers don't know what five sevens are - and that's only arithmetic.

I once asked a prospective Member of Parliament just before a General Election what seven nines are. He didn't know. He lost his £500 deposit. Didn't get enough votes. Otherwise he might have ended up as Chancellor of the Exchequer.

I deliberately avoided graphics. Graphics depend on screen driving software thus losing portability between machines.

My favourite Victorian is Oliver Heaviside. He invented the beautiful Operational Calculus which magically transforms ordinary calculus into simple algebra and converts functions of frequency on transmission lines into functions of time. Now everything is going digital at Megabits per second he was about 130 years in advance of his time.

All the best to you and yours.

Reg, G4FGQ.

3688. SA602A oscillator load capacitance

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-07-11 22:37:55 UTC
From: Ben Jackson <ben@ben.com>
Message-ID: <slrneb8a23.1gh6.ben@saturn.home.ben.com>
Source record: 11288

I'm trying to figure out the load capacitance of the oscillator pins 6
and 7 on the SA602A. I've got a 14.85MHz fundamental crystal with a
specified load capacitance of 13pF running about 1300Hz slow (with
27+22p). The datasheet doesn't say much about the oscillator pins.

The best hint I've found is about the SA605:

From AN1994 about the SA605:

Because the Colpitts configuration is for parallel resonance
mode, it is important to know, when ordering crystals, that
the load capacitance of the SA605 is 10pF.

That would suggest I'm way, WAY off, and my external load capacitors
should only amount to 3p!

The SA612A datasheet has an example where it specifies the crystal load
capacitance, but then it doesn't specify C1/C2 values. Then it has
another example with specific values for C1/C2 (which are 4.5p in series)
but does not mention the load capacitance of the 3OT crystal. One at
that freq made by CTS has a load capacitance of 13p, which would suggest
that the oscillator is about 8.5p. The 602A has a similar example with
another unspecified crystal...

Ben,

When a crystal manufacturer specifies a load capacitance for a crystal, it is usually a good indication that the crystal is meant to operate in the 'parallel resonant' mode. This is a very misleading term however, as the quartz blank only has one pure resonance, and that is a series resonance. However, the equivalent LCR circuit of this series resonant circuit will look like a capacitive or inductive reactance at frequencies removed from the series resonant frequency. At some frequency, the crystal will look inductive enough to resonate an external capacitance of a value specified as the 'load capacitance".

Your crystal will will form a parallel resonant circuit at the marked frequency with an external capacitance of 13 pF. This is fairly low, as most crystals are specified for 20-32 pf loads. If your circuit already has too much capacitance, you can lower the net capacitance seen by the crystal by either using a small coupling cap whose value in series with the circuit capacitance equals the load capacitance, or you can put an inductor across the crystal whose value in parallel with the circuit capacitance will result in a net capacitance value equal to the 'load capacitance'. In the former case, the low value of coupling cap could cause an AC voltage drop that might prevent the circuit from oscillating. In the latter case the added inductance could cause a spurious oscillation at an unintended frequency.

All things considered in your case, I'd use the series coupling approach.

3690. Re: 2MHz stepup transformer formula ?

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-07-12 00:20:16 UTC
From: K7ITM <k7itm@msn.com>
Message-ID: <1152663616.663886.100710@p79g2000cwp.googlegroups.com>
Source record: 11291

I've had some experience driving quadrupole ion filters...

I would guess you would do best with a high Q tank circuit driving the ion trap through as short a length of wire as possible. Keep the tank and the wiring very well balanced with respect to stray capacitance to ground, especially. You can use a link to couple RF energy into the tank circuit. The capacitance of the trap is probably enough to resonate the tank coil. You can split the coil into two halves, with the "hot" end of each half going to the ion trap, and the "cold" ends connected together with a bypass capacitor; then you can apply DC across that bypass capacitor, and the DC will be carried directly to the ion trap. I am assuming here that you want to drive your trap in the normal way, with a combination of RF and DC. It is usual to use feedback to maintain an accurate RF voltage. You can add small capacitors, one from each "hot" lead to the trap, back to a rectifier with low input impedance. The capacitor impedance then sets the voltage to current conversion ratio, and will be frequency dependent of course.

If you use a resonant tank circuit with a loaded Q (nearly equal to the unloaded Q) of, say, 250, and you have net capacitance (ion trap plus wiring plus coil plus voltage sampling capacitors) of, say, 32pF, and the operating frequency is 1MHz, then the tank impedance across the trap will be about 250*5k, or 1.25megohms. At 500V RMS, that's only 0.2 watts. It appears that your signal generator can put out 1 watt, so it's quite possible that your signal generator can drive the tank without an amplifier. You can experiment with links (one turn, or a very few turns, over the area of the tank where it is split in two) to see what gives best results. You can vary the coupling by adding a variable capacitor in series with the link to the generator. Proper adjustment will give you a 50 ohm load for the generator, at the tank's resonant frequency. Winding a modest size tank coil with such a high Q at 1MHz is not trivial, but certainly possible.

With such a resonant tank circuit, which is useful both in getting high voltage and in reducing harmonics in the drive, it will be difficult to operate over such a wide frequency range. Do you really need to do that? If you do, I would advise you to add a medium-power amplifier between the signal generator and the step-up transformer, and beware about a lack of harmonic filtering as a result of your broad-band circuit.

Further details about exactly what you are trying to accomplish might be helpful.

Cheers,
Tom

Two potential problems. One is that the field isn't completely contained. Leakage is greater with more sparsely wound toroids and ones with lower permeability cores. The second is the "one turn effect" - There's a net field equivalent to that of a single turn running circumferentially around the core. A solid plane parallel to this would act as a shorted turn. Both effects would act to lower the Q, and might be the cause of some drift or microphonics if the inductor was in an oscillator tank.

But to be honest, I've never run any experiments to see just how much of a problem it might cause -- it's quite possible you could get away with it in some or even most applications. I'll put it on my list of things to do when time permits -- unless somebody else is willing to take on the job.

If you are set on the garage, the insulated door will do wonders. I replaced my old wooden door with plenty of holes and spider access, and it was the best thing I ever did lately!! I can work in the garage with a couple of fans running. It can get cold here in western NC, but in fairness I must mention that my garage and shack is downstairs and partially underground.

Another suggestion to consider is one I used in a previous house: a spare closet! I put a desk in the closet with a hutch. There was enough room for all the radios, and when I was thru radio-ing, I could push the chair inside the closet and close the bi-fold doors! No one was the wiser!! People could come visit us in the den and never know there was a fully stocked radio room on the premises! My wife always joked about putting me in the basement, the dog house, or a closet. Now it was TRUE! :)

I'm reading David Rutledge's excellent "The Electronics of Radio."

In Chapter 10 -- Power Amplifiers, he discusses Class C amps and says, "In addition, if we drive the transistor clear to saturation, using the transistor as a switch, the dissipated power can be greatly reduced, because the saturation voltage is low. This is Class C amplification..."

I'd always throught that in Class C, while you'd operate the device so that it was cutoff during most of the cycle, but not saturated.

Is this just a different definition of Class C?

I checked back with SSDRA and EMRFD, and didn't see anything about driving Class C amps into saturation?

What says the group? Do we saturate in Class C or not?

The Class C transistor amplifiers I design and use most certainly saturate. I believe that's standard practice for solid state amplifiers. I don't think tube type class C amplifiers are or were typically driven to saturation, but I honestly don't know for sure.

The classic definition of class C involves only the fraction of the cycle during which it conducts (< 180 degrees). There's no restriction on how hard it conducts.

And as a followup, is the power dissipation in the final controlled
by the duty cycle of the pulses (or number of degrees of conduction
more generally if the input is not a square wave)?

3697. Low cost SMD Oven for making SMD samples and Prototypes

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-07-12 10:54:52 UTC
From: erica <erica@auto-system.com>
Message-ID: <1152701692.603004.306280@35g2000cwc.googlegroups.com>
Source record: 11198

This SMD Oven Controller (SMDOC-01) is designed to use with a toaster oven. It provide a low cost solution for making SMD prototypes and samples. The temperature profile is similar to the expensive industrial SMD oven provided. So, the sample quality is as good as the industrial oven can do. It is capable for packages including 0402, BGA, QFP, SOP, SSOP, TSSOP, SOT, etc. It is an indispensable tool for R&D and making samples. It is very suitable for electronic companies, laboratories, universities and hobbyists. SMD Oven Controller (SMDOC-01) is only US$206, including oven (PCB size is large up to 19 x 17cm) is US$283. Voltage 220V, 8A fused.

Features:
1.Small, low price, performance comparable to expensive industrial SMD oven.
2.Capable for any SMD packages. An indispensable tool for R&D, sample making and small batch production.
3.No hand soldering. No painful. No difficult. Save time.
4.Connectable to PC via RS232 for profile setup and temperature monitor. It can also operate independently without PC.
5.Simple to use. LEDs indication for each stage of pre-heat, soak, reflow and cooling. Alarm and power cut off after finished.

Product information : http://www.auto-system.com
Please send me email : erica@auto-system.com for any inquiry or order.

There's a much simpler and cheaper solution for experimenter 'one- off' board soldering. Just solder all the part leads to the board without worrying about solder bridging. After you're done, come back and wick off all the excess solder with solder-wick. This will remove all solder bridging, but will leave a good strong solder joint between the part leads and the board pads. Of course it only works on parts with exposed leads, not BGA's etc.

I've not tested for Q degradation but the added capacitance and chance
for movement makes VFOs far more unstable. Microphonics from

movement are part of the problem but if glue is used that goes away and the stability of the glue with temperature is then an issue.

The single turn field while small is likely related to the number of turns and with fewer turns I'd think even a modest distance such as 0.1" it would not be a significant factor.

Saturation is itself a somewhat mushy point. There's a V_sat specified on the datasheets but the actual definition of saturated is entirely application-sensitive. As a practical matter as you add more base current you will go further into saturation (up until you melt the base-emitter junction and then all sorts of wacky things ensue).

Choice of drive level and output level and load impedance in a Class C amplifier certainly will in many cases put the device into saturation.

"One turn effect" in magnetic core computer memory?
Miniature toroids single-stitched and woven with wire:

http://www.fortunecity.com/marina/reach/435/coremem.htm
What's the Amidon number of these cores?

Some electric guitar tube amps used perpendicular
point-to-point wiring in 3-dimensions between
terminal strips to minimize inductive and capactive
crosstalk. They are amazing to see.

For operation at HF and higher, it's not always that simple.

For anything but the lowest-speed PWM/class C/class D/class E
operations, the transistor switching time (and the influence of the
load on the switching time) can be a most important contributor to
power dissipated in the device.

An indication of the "bare transistor" switching time can be found on
the datasheets as the delay time, rise time, and most importantly
storage time and fall time.

Very closely related if you are operating anywhere near max power
dissipation or max current is the SOA curve.

Tim.

3703. Surplus Sales of Nebraska

Newsgroup: rec.radio.amateur.homebrew

I, like many hams, have gotten a lot of surplus stuff from Fair Radio Sales in Ohio.

Monday, I discovered Surplus Sales of Nebraska.

Nice people! Old school customer service. The web ordering isn't "modern". But they don't make a lot of money at this, I'm sure. So I.T. people are probably out of the question. But your order gets underway in about 48 hours.....

They told me the owner spends all day on the net trying to hunt down surplus stuff he can buy. So if you have anything, I was told to take a photo of it....and send an e-mail to him. His e-mail address is at the bottom of every web page.

Here's the website for Surplus Sales:

http://www.surplussales.com/

Different animal. Those cores have a high remnent magnetism
and a very hard BH curve. The initial ui is far higher than common
ferrites used in RF today. Some were nickel based steels in very
thin foils wound as 50-200mil toroids. The idea is you write them
with a lot of current (for a 50mil core around 2-300ma) and read them
by "writing" them with an apposing polarity pulse, the size and
timing of the pulse returned is a 0 or 1 after amplification and
slicing. The key is you always get a pulse during read but it's about
3-5x bigger and delayed in time (25 to 300ns depending on core size,
temperature and material) _if_ the core was written in with the
opposing magnetic polarity. Typical cores such as used in DEC
pdp-8E had a memory cycle time of 1.6uS (read, modify, write) as a
read is destructive and requires a write cycle to restore the data.
That was typical speed for core memory of the day (1970).

If you want to try this for yourself (1bit memory) a nail or better a
peice of hypersil (transformer core material) with a few turns of
wire, compass and a scope will demonstrate it. The test will be to
find how much DC current will magnetize it then find out how much it
takes to reverse the magnetism (compass helps here). Then you add a
few turn sense winding and watch the pulse that results when you
magnetize it with a given polarity, repeatedly. Then reverse the
power and hit it and the resulting pulse will be later in time and
bigger.

>Some electric guitar tube amps used perpendicular
>point-to-point wiring in 3-dimensions between

>crosstalk. They are amazing to see.

Different animal, thats called cordwood construction and its
also for space savings and affords mechanical ruggedness.
Early aerospace systems were built that way for size. Problem
is they are impossible to maintain and heat is problematic for
larger cordwood.

Neither directly relate to the concept of an tuned toroid inductor
in proxmetry to other conductors/metal cases/ inductors.

Not really, although it's a factor. What counts more is the transistor voltage when the current is maximum, and the relationship between V and I during switching. This in turn depends on the nature of the output network among other things. If you really want to find out more about the efficiency of a saturating transistor amplifier, look up some of the papers on "class E" operation by Sokal & Sokal and by Raab. They basically took a time-domain approach to find the optimum conditions for maximum efficiency of a saturating class C amplifier. I've never consciously designed a "class E" amplifier, but have gotten more than 85% collector efficiency from saturating Class C amplifiers at the 10 watt input level.

Bull. SS of N is one place I will never buy from again. They do not remove out-of-stock items from their website when sold out, but they continue to take orders for them. In a couple of days, they notify you the item is no longer in stock, thereby wasting your time you could have spent looking elsewhere. This has happened to me several times.

Actual phone conversation:

Me: Can you check stock on part number xxxx?
Them: No.

No explanation, no "sorry", nothing but "no". These are not my kind of people.

Bill, W6WRT

3708. What is a wire antenna's impedance? -followup

Newsgroup: rec.radio.amateur.homebrew

From: John - KD5YI <groups5munge@verizon.net>
Message-ID: <7T9tg.15155$Wh7.1326@trnddc07>
Source record: 11209

Additional response to OP jo9s8as at yahoo.com:

Using an MFJ259B with a #14 AWG (.064 dia) copper wire 19.4 inchs long stuck into the antenna connector, I measured the following...

f = 146.5 MHz
R = 64 ohms, X = 65 ohms
both hands holding the MFJ

f = 146.5
R = 43 ohms, X = 60 ohms
one hand holding the MFJ

Sat the MFJ down on a brick wall about 3.5 feet high and moved away from it.

f = 146.5
R = 34, X = 44

Same location, adjusted for minimum SWR

f = 153 MHz
R = 61, X = 25

This last reading was a bit difficult as the readings changed with my body location.

I could never determine the sign of the reactance for sure and I was never able to adjust the frequency so that the reactance reading was lower than about 25 ohms.

The MFJ enclosure is about 6.75 x 2.375 x 4 inches.

Cheers,
John

> Bill, W6WRT

I find it odd that the original poster felt a need to post about the
company to three different newsgroups (likely bad enough that he
felt the need, made worse by doing multiple posting), especially
given that the company has been around for decades.

I remember when I first saw an ad for the company years ago, and thought
"wow". But when I got a catalog, I felt the prices were outrageous.
Maybe if you want to rebuild a KWM-2 to out of the box standards you're
willing to pay large prices for the exact knob, but as a surplus outlet
I felt there were better prices elsewhere.

Because when you see the word "surplus", you immediately think of
low prices compared to new stock.

Sphero,

The way Japanese read Chinese chracters is done in two ways.
1. Something resembles the original Chinese pronounciation at the time
Like Hitachi's "Hi" part.
2. Ancient Japanese word adopted to a Chinese chracter with same meaning.
Like Hitachi's "Tachi" part. This means "standing", as you mentioned.

Hitachi is the name of the city where Hitachi originated as a repair
facility for the mine there in 1910.

Mazda is actually "Matsuda", which is composed of "Matsu (pine tree)" and
"Ta (field)". "Ta" changes to "Da" when it is attached to some other
character (sorry, forgot how is called in English). "Matsu" and "Ta" are
both from ancient Japanese words.
Alps is named after the English term "Alps".

Hope I'm not confusing you even more!

Regards,
Satoru

A lot of old-line surplus businesses do not fare well with the expectations of the modern order-it-today-get-it-tomorrow-morning world.

Some other businesses (e.g. Digikey, which was not always a big business, think back to their QST ads 30+ years ago where their only product was - gasp! - a digital keyer) have made the transition remarkably well and are in fact the benchmark of a modern catalog parts house.

I think it is still valuable to have the "not really sorry" surplus places remain in business though. I've dealt with them long enough that even when I don't get a "sorry" I think I understand where they're coming from - and in many cases I also know who to ask for who knows the real story. The part-time help at the order desk is unfortunately not as good a resource as the guy who's been running the business for 30 or 40 or 50 years.

I like that idea, since the series capacitance reduces the effect of
unknowns on the oscillator side. Using my estimate above and given my
existing caps, I tried a 33p in series and got to 14.849995MHz, which
is a vast improvement.

Thanks!

I've always been curious... places like All Electronics and MPJA and Hosfelt and ... that one near Dayton ... where did they find all their surplus *before* the Internet? There must have been publications or something that dealt with getting rid of surplus electronics?

They were on auctioneer's mailing lists, as well as the US government surplus sale mailing lists. JIT manufacturing and lots of custom parts has reduced the available surplus quite a bit. I watch Mendelson's (in Dayton) change over the years from mostly military into industrial surplus, and the way they treated customers changed as well when the founders died off an their kids took over.

3715. Re: Toroid or molded inductor in low voltage tank?

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-07-12 23:39:54 UTC
From: K7ITM <k7itm@msn.com>
Message-ID: <1152747594.902517.174460@35g2000cwc.googlegroups.com>
Source record: 11216

Well, it's less of a problem than I'd have guessed. It turns out that I was already set up to measure inductance and Q of little toroid coils, since I'm winding some for some filters. These are on T25-6 cores. The one I measured for the results below has 22 turns of AWG28 wire on it, essentially evenly spaced around the core, with a gap of about 45 degrees between the wire ends. That is, the wire occupies about 7/8 of the core. I won't claim high absolute accuracy, but the Q measurement should be well within 10%, and the relative accuracy (from one condition to the next) should be much better than that. In particular, I can guarantee the direction that Q moves as I add shielding. The first measurement is with the toroid inductor standing vertically off a copper ground plane, with the core at the gap in the winding about a millimeter up from the plane. The second measurement adds a piece of copper foil tape stuck to the ground plane, and bent up at right angles to the ground plane so it's immediately adjacent to one side of the coil. The third measurement folds the copper foil over the top of the toroid and down the other side, so the coil is surrounded by copper foil. These are labelled 1, 2 and 3 below.

Inductance Q
1 1.355uH 160
2 1.349uH 158
3 1.335uH 157

The actual drop in inductance is almost certainly a little more than indicated. That's because the copper foil adds capacitance, which would lower the resonant frequency and be seen by my measurement technique as increased apparent inductance. I could resolve that by making a similar measurement with lower resonating capacitance, but I'm not set up to do that right now. Of course, the lowered inductance is because the shield reduces the volume occupied by the magnetic field, so there is less energy stored in it for a given current. But these measurements tell me that even for the low-mu type 6 cores, there is quite a low external field.

Cheers,
Tom

The normal US home has two sockets that provide 220 V -- one for a
kitchen range and one for a clothes dryer. Both are big (like 30+ amp)
connectors. So, yes, it is a problem.

Not true at all!

220V outlets are very rare in residences - no need for them as 220V is only used for very high power equipment. The exceptions would be central air conditioners, electric stoves, electric water heaters, but these are typically hard-wired in a junction box. Run-of-the-mill appliances using up to about 20 amps are usually run on 110VAC

In order to get any semblence of efficiency, the drive waveform should drive the stage from near-cut-off to near-saturation, somewhat like a switch. However, depending on how hard the sinusoidal input signal drives the "Clacc C" stage, the conduction-angle and thus the duty-cycle of the output (before filtering) will increase or decrease, resulting in variable output power in the load.

Does the above mean that radio hams with a 1500 W RF (legal limit) power
Amplifier will need an additional dedicated 220-234 V outlet in their
shack ? Or would such an outlet be available anyway in relatively new
houses ,built after say 199x ?
Just 2 questions .

ALL us homes have 220 brought to the fuse / breaker box. It is a 220 volt, center tapped transformer on the pole and all three lines are brought to the breaker box. . Each half of this winding supplies the 120, 110, 117, whatever you choose to call it. Half of the circuits in your home come from one of the winding ends (phase) and the center tap is connected to the common; the other half come from the other "phase".. Therefore you have two phases of 120 and they are 180 degrees apart. Some call it single phase, I think it should be called two phase...cuz it is. (:-)

If you really need to get 220 quickly and easily [and do not draw more than than the 15 or 20 amps of your brealers] you can find two outlets on the two phases and get one half of the 220 from each.
I did this for a visiting relative from Germany so he could run his electric shaver. It is still the talk of the relatives...
Since I built my house and did the wiring with Dad's help, I kept a drawing of all the circuits, I knew that I already had two phases in the guest room. A couple of cheap extension cords was all it took, with one blade of a "three prong adaprer" inserted into each hot side of each extension. Guest 220 in 5 minutes!

I'd feel ok drawing 8A this way, but you shouldn't try this at home...I'm a professional. (:-)

Linears should have either
1- both 110 and 220 internal wiring options, or
2- just 220

But 120 is is a real stretch.

73, Steve, K9DCI

Hi,

I was wondering if anyone here might have some good ideas regarding promotion of our web site.

The company was formed mainly from a technical base and one of the weaknesses is learning how to let others know we are here.

I believe we have an excellent range of wireless solutions that have been designed to provide robust and reliable performance. The initial customers be have serviced to date are happy with our products but we need a larger customer base to survive.

The site was constructed by myself but as I am not particularly experienced with web design it has plenty of room for improvement.

Currently the only advertising I use is per click on yahoo and google.

Thanks in advance for any constructive comments that may help point me in the right direction.

Even some comments on whether the site is appearing correctly in your browser or comments on ease of use, clarity etc. (Still completing photos and datasheets so some pages are acting more as place holders while I complete the information.

--

Kind Regards

David

The 'power dissipation' in a Cass C stage is primarily a function of what percentage of the cycle the stage is neither in saturation nor cutoff. A perfectly rectangular output switching waveform of any duty cycle , if it could be achieved, would result in nearly 100% efficiency.

Who said the drive had to be sinusoidal? If the final can run almost square
wave, why can't the driver?

Unfortunately, it makes a terrible mess of any modulation.

To avoid distortion and non-linearity, saturation can be permitted
only on the extreme peaks of the modulated driving waveform. Class-C
is ruled out. Class-B or Class-AB prevails.

Reg.

My recollection is that Classes B and AB are used for AM and SSB,
while Class C works fine for CW and for FM.

Yes, exactly. We just assume sinusoidal drive because that's the most common
case

Reg,

Well not ANY modulation, just signals with amplitude modulation components. But this is a well-known property of Class C amplifiers, so what's the point?. If we want to talk about Class B or Class A, we should start a new thread.

3734. toroid cores?

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-07-14 09:42:06 UTC
From: nospam@geniegate.com
Message-ID: <Lc1152868412193490xc2a48c@air.tunestar.net>
Source record: 11236

Hi Newsgroup,

Been trying to make a regen radio out of garbage. So far, I seem to have all the parts and it almost seems to work, however, I'm a bit confused about the inductance of toroid cores.

I've tried to use one of those things from the back of a monitor (presumably to prevent RF interference) as one of the coils and another adjustable coil from another device, to no avail. It has no markings and it appears to be a ferrite device in the shape of a ring.

Anyone know an easy way to figure out how many turns to get (presumably 300mh?) from one of these? Can I measure it with a ruler and some how get a formula for the number of turns / mH ? Are these really bad deviced to use? (the thought occurs I must admit, that if it was meant to BLOCK rf, using would be illogical)

Here's the circuit I'm basing it on:

http://www.tricountyi.net/~randerse/regen.htm

If I inject a signal directly into the coil (in place of his amplified RF "front stage") I can pick it up, but no oscillation and lousy tuning. (comes in on pretty much 1/2 the dial) I'm assuming this has something to do with the tank circuit. (I have two air capacitors totalling around 360pf one from a console stereo, the other from some place I can't remember where..)

He's got 25T and 23T specified for a T-50-2 coil. Closest research on these that I can find is that this should produce about 300mh (but I could be wrong! anyone know for sure what the mH is on that?) This seems to make sense from everything I've read so far, but.. I have no way to measure it.

If I end up using an air core, would I keep the ratio of turns for the tickler and injection coil? (where he has 3 and 5 turns spec'd) ? It's my assumption that in these two smaller coils, it's a step up transformer so it'd be a matter of ratios, am I correct in this assumption?

Every bit of the circuit should come from garbage (the MPF102's I had to buy, but thats it) Even the coil wire is from the transformer of a broken microwave, the LM386 chip used for audio (and some resistors) will come from an old modem and the pot is a 500k pot, (from a console) wired in parallel with a ~>10k resistor to give a range between 0 - 10k ohms.

The main point is to build it from garbage, I already have a radio and don't really "need" one, but.. as I once built a tube version of this (far simpler) doing one in solid state appeals to me.

Check this page from Amidon Associates. They are a great supplier of
toroids to the ham community!

http://www.amidoncorp.com/aai_ironpowdercores.htm

Looks to me like 25 turns on a T-50-2 core will give about 3 MICRO
Henries according to Amidon's formula...

======================
Steve , Tnx for providing the 'full' picture.
Assuming a 67 percent efficiency (am I too pessimistic?) a legal RF
power amp would need 1.5*1500 = 2250 W (say overall maximum of 2400W)
which at 220 V means 12 Amperes.
So, a shack without 220 -234 V power supply would need a dedicated
supply from the switchboard .

Here in the UK we do have 115V industrial power tools,which need to be
used with a 230/115V (usually portable) safety transformer with the
secondary having an earthed centre tap ,such that in the event of a
'fault' personnel is exposed to a (peak) voltage not exceeding 1.4*58 =
81V which is considered sufficiently low to prevent electrocution.

The nominal domestic supply voltage within EU countries has now been
'normalised' to 230V ,meaning that (within a voltage band) the same
equipment can be used in all the countries.
Before , the UK had 240V and continental countries 220V . This often
meant that for example an (clothing) iron for 220 V had a very limited
life when used in Britain .
The voltage at my place (rural area) is nowadays usually 236-237 V
,whereas earlier it was up to 250 V or sometimes even higher.

=======================================
All power amplifiers have a tuned circuit in the plate. It is
essential to reduce output power contained in the harmonics.

In any case, power in the harmonics is wasted power.

With a tuned circuit in the plate it is impossible to achieve a
rectangular voltage output waveform. It is always a sinewaveform.

A rectangular plate current in conjunction with a tuned load always
causes harmonic power to be wasted at the plate.

So one might just as well use a sinusoidal driving waveform, Class-C
or not. It's easier. It also avoids generating and wasting harmonic
power in the driver.

Yes, I would expect they would be really bad ! If you knew the
permeability of the material used then measuring with a ruler and
applying some math (I don't know the formulas) would in theory get you
an iductance calculation. But the materials used for these EMI chokes
generally has too high a permeability to make inductors with convenient
numbers of turns for the HF bands, and generally is quite lossy so the
resulting inductors will have low Q. It is extremely unlikely to work.

Since you don't want to buy any parts, I would recommend once you
figure out the required inductance from the Amidon formulas, just wind
air core coils (well, some sort of low loss former like a piece of
plastic tubing is probably needed) with the same inductance.
Inductance formulas for air core coils are available everywhere in
handbooks and on the web. You might have to play with the number of
turns in the feedback link though, as the coupling between it and the
main coil will not be as tight in an air core coil as in the toroid. I
would start with the same ratio of turns or maybe add a bit to the
feedback coil.

If it's a broadcast band radio a toilet paper tube will work well. If
ham band then something smaller like a sample-size shampoo bottle.

Does it count as garbage if you buy the stuff so you'll have the
'garbage' when you're done?

23-25 turns (or 50 total) on a T50-2 would be more like 20 uH
(micro henries).

If you using a ferite intended for noise suppression then its likely
43 ot 71 material and not suited for RF tuned circuits.

Why not wind the coil on a toilet paper cardboard tube, pill bottle,
or peice of PVC pipe scrap?

There are toroid cores that would work quite well for this, but the characteristics of the core depend heavily on the core material. It can be very difficult to characterize a mystery core.

I suggest you look in the ARRL handbook for the appropriate coil formula (or search the web) and make a single-layer air core coil on an appropriate-sized form.

LOL!

I was sooo tempted to buy 0.05 resistors after burning my fingers trying to extract them from a modem.. :-)

I read some place, it's better to use a larger diameter coil if at all possible, but the formulas I've run across for calculating uH (I always get my milli's and micros confused!) seem to indicate in either case, I'd need the same amount of wire.

Lots of things puzzle me about this, for example in this circuit:

http://www.tricountyi.net/~randerse/regen.htm

I don't see a "grid leak" the way I had used in the tube model.

While this circuit:

http://www.electronics-tutorials.com/receivers/regen-radio-receiver.htm

Seems to have one feeding the gate of the FET. (never was real clear on what it did exactly)

(I can't use the latter circuit as it has more parts and I don't want to introduce a 3rd variable cap.)

3744. Re: toroid cores?

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-07-14 15:13:06 UTC
From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <K7CdnSpNjfn8KCrZRVnyug@bt.com>
Source record: 11245

The inductance of a toroid, in MICRO-henries, is -

L = 0.6283 * Mu * Square(N) * B

where

B = D1 - Squareroot(Square(D1) - Square(D2))

Mu = permeability of core material.
N = number of turns.
D1 = mean diameter of ring in metres.
D2 = diameter of ferrite core material in metres.

If the core is not circular, use the equivalent diameter which has the same cross-sectional area.

To calculate number of turns just rearrange the formula.

To obtain high Q, you MUST use HF grade permeability material.

Permeability can be calculated using the formula by winding some turns on a core and measuring inductance. A very good instrument to use is an Autek RF Analyst-1

But, of course, if you are able to measure inductance there will be no need to calculate permeability. You can calculate the required number of turns immediately.

>Henries according to Amidon's formula...

Whew! thanks!

My assumption that it was 300 yielded some pretty far out number of turns for air coils, like 72 or something I seem to recall.

Looks more like 7-8 turns on a cylinder 2.5" in diameter? (that seems awful small to me) If the tickler coil is currently three turns, would I just leave it at that? Still, it's nice.. small enough I can probably use the "good wire" for shortwave. :-) (FWIW old microwaves are apparently an excellent source if copper wire, I'm tempted to use some of it for an antenna)

If the capacitance in the tank circuit is ~25-400pF, and I use 3uH then the frequency response will be about: 4.5mhz - 14mhz ? (does that sound right?)

This must be why the others I'd looked at involve pluggable or tapped coils?

(In general, is there an ideal ratio of capacitance to inductance for a given range? IE: could I just add parallel capacitance to lower the frequency or is it better to increase the coil or.. both? I notice as I run through some calculations, I need a LOT more uH to cover a smaller and smaller range of frequencies the lower I get.

He states on his page that it picks up MW, (which is actually what I'm mostly interested in) but.. didn't mention anything about mixed coils.

His circuit involves a "front end RF amp" (for a total of two coils) when using air, do I need to some how shield this second coil? I'm assuming it if it's perpendicular to the main one, thats enough?)

Was hoping to avoid a large air coil because as it is now, the everything except the capacitors (and AF stuff) fit in a tunafish can for shielding. :-/

Still, the whole point is to assemble it from garbage. I might splurge and get some mechanical stuff for the tuner, but.. have to get it working first! (sure am glad I kept that signal injector, it's been really handy for this!)

Hi, Allison -

I think you erred slightly. It's about 3 uH at 25 turns on a T-50-2. See Scott's post in this thread for a link to data and equation.

Cheers,
John

For 23-25 yes, but I also postulated that was a tapped coil of 50T
total. then I'm closer. But it was an eyeball guess as I didn't
calculate it. I was only off by ~7 rather than 10,000. ;)

In the cell phone base business, everything (almost) runs off battery
systems.

There were two cases where Development Engineers not knowing about our mains system, where developing products never before run off the mains.
In one, the presence of "both" 120 and 240 was causing some spike absorbers, designed for 120 systems, to pop from the 240.

The other was a small base station which had its power input connections designed by Mechanical engineers. It came to my test group without the power cord connected to the black (protorype) "barrier terminal strip". One of the Develpoment Engineers called another for the connections and made them. It was plugged in, but wouldn't work. Several Engineers started checking and discuvered that the serial port on the control laptop had been fried. Several of us put our noses to the connector and could smell the burned components on the unit. We also noticed that the heat sink wasn't getting warm. I and several Engineers put our hands on the case to test this.
Note: In the US, we have a third wire in all outlets which, though it is the same as the common or neutral (basically also ground or no potential) side, it is used to connect to any exposed metal parts. The purpose it to divert any hahazzardous shorts to ground and blow a breaker or fuse rather than harming someone. We were focused on finding the cause. Several of us worked trying to analyxe the failure and found the serial interface of the unit has fried as well as the lap top serial port.
Findings:
The HOT of the 120 (instead of the safety ground connection) was connected to the chassis. This placed the outside of the (as yet unpainted) housing at 120 VAC relative to all other grounded equipment in the room!
I was one of several who put his nose up to that hole to smell burnt comopnents. I was one who felt the unit for heat build up.

It hit me half way home. Needledd to say, I gave the Mechanical and Electrical Engineers a lecture on mains principles.

Using two outlets without some logic to make sure both plugs are
connected is a very dangerous setup. The simplest setup is three
relays, two to detect the 120 VAC on each cord that together energize
the 240 VAC outlet.

I wouldn't blame the mechanical engineers. I'd blame the engineering manager
who let mechanical engineers design an electrical interface, and then
apparently didn't design-review it.

SolderSmoke!
A SHOW FOR ELECTRONICS HOMEBREWERS!

http://www.ourmedia.org/node/247756

Topics discussed in SolderSmoke #27:

-- Computer woes
-- Bill's visit to the Dominican Republic
-- Building Xtal oscillator with kid
-- Book Reviews:
"The Art of Electronics"
"The Electronics of Radio"
-- Ether and Quantum Mechanincs, Tao of Physics
-- SolderSmoke Mailbag: Nigel in Dover, Mike WA6AWA, Matt KC8COM

CHECK OUT A PICTURE OF SOLDERSMOKE'S LONDON STUDIO:
http://usgadgeteer.blogspot.com/

Listen at: http://www.ourmedia.org/node/247756
Background:
Tired of listening to Led Zepplin or NPR on your
I-Pod? Wouldn't you like to be able to carry with
you the kinds of ham radio conversations that you
listen to while in your radio shack?
Mike, KL7R, in Juneau, Alaska, and Bill, M0HBR, in
London, England meet regularly on the ECHOLINK system
to discuss their homebrew radio projects. We are
making them available as PODCASTS.

NEW RSS FEED: You can subscribe to the program, have
them downloaded to your MP-3 player, and listen to
them at your convenience. To subscribe, just cut and
paste this URL into your I-poder (or similar)
software. We've been having trouble with our Ourmedia
RSS feed, so Mike (software wizard that he is) has
homebrewed his own RSS feed. In order to subscribe to
SolderSmoke, point your podcast software to:

http://kl7r.ham-radio.ch/soldersmoke.rss

If you don't have an MP3 player you can just go to the
site below and listen to the latest program (and
earlier editions) using the audio software on your

computer.

http://www.ourmedia.org/node/247756

Here's the homepage for our show. All our programs are available here. There is also a blog and links to some of the sites and documents we've been discussing: http://www.ourmedia.org/user/36170

We hope you enjoy the program. Please send us feedback.

If you get an electric shock in your nose, I would suggest that you do
not drive a car for a few hours.

I was building a power supply and fired it up for the first time and
was sniffing for any hot components. I then actually hit the hot side
of the power transformer primary terminal (220 V over here in those
days). It was a nasty shock and when driving the car soon after, I
really had to concentrate to keep the car in the middle of the
lane:-).

This comming Sunday...

+++ Now even more Buyers Parking !!!
Thanks to Shire we have use of their new parking lot
across Albany St from the SWAPFEST !!!

!! ** More Buyers PARKING is available ** for details see
http://web.mit.edu/w1gsl/Public/flyer

*** !!!! In our Traditional GARAGE and the adjacent lot !!!! ****
so come rain or shine or super heat the Flea is on !!!

********* $1 buyers discount with hardcopy of this notice ********

COMPUTERS - ELECTRONICS - HAM RADIO - COMPUTERS - ELECTRONICS - HAM RADIO

FLEA all SUMMER at MIT
Sunday July 16th 2006
9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take
place on the third Sunday of each month this summer,
April thru October.

There is tailgate space for over 600 sellers and
free, off-street parking for >2000 cars!

Buyers admission is $5 (you get $1 off if
you're lucky enough to have a copy of our ad)
and sellers spaces are $20 for the first and
$15 for each additional at the gate.

The flea will be held at the corner of Albany and
Main streets in Cambridge; right in the Kendall
Square area from 9AM to 2PM, with sellers set-up
time starting at 7AM.

SEASON PASS + Advance Seller Discount

A sellers discount season pass is available which
offers a 30% discount. By prepaying you get a
discount and earlier admission. See the registration form.

*** Attention Sellers ***
Prepaid vendors.. Season Pass or monthly,

will be admitted FIRST.
Separate lines will form prior to gate opening
for prepaid and nonprepaid vendors

!! RAIN or SHINE !! Have no fear of rain, a covered
well illuminated tailgate area is available for all
sellers (6'8" clearance).

Talk-in: 145.23- (PL 88.5) W1BOS/R and
W1XM/R-449.725/444.725 (PL 114.8/2A).

Sponsors: MIT Electronics Research Society
MIT UHF Repeater Association (W1XM)
MIT Radio Society (W1MX)
Harvard Wireless Club (W1AF)

For more info / advanced reservations 617 253 3776

Look at the crappy no name coax and super cheap connectors on their
website before you decide anything. BTW, they have a very bad
attitude. One of their salesmen was on one of the sci.electronics
groups telling people off.

Thanks.

Looks like I may have fried the FET. :-(

No matter what I did, I simply could not get feedback. I hooked an LM368 audio amp pretty much directly to the RF signal generator and I could vaguely hear it, so... I'm thinking the reason it was working the way it did (with the "station" comming in stronger as I tuned it) was simply the LM386 acting like a detector in a TRF radio :-/ (The thing that confused me was, if I held an AM radio really close to the coil, I DID get some interference, but I couldn't hear a squeal in the speaker of my radio.

I put it away for now, I do have another FET I could f^Htry, but.. I don't want to damage it.

I was thinking about removing the pot entirely and using a rotating "inner coil" serve in it's place:

+v ------> (tickler coil) ---> [D|G|S] ---> audio out

(Basically using both sides of the FET)

Hooking the tank circuit up to the gate, just as before but eliminate the parts for controlling the tickler, sort of like this:

<()> with < > being the tank coil and the () being a coil inside the <>'s in such a way you could turn it, controlling the tickler by changing it's angle.

I've seen old regen radios that appear to do something like this, but constructing a coil that can be turned (w/out changing the tank and input coil's value) look tricky. A plastic ink pen could be the shaft for turning it, but keeping it in the center w/out wobbling..

As the parts MUST come from garbage, precise values are hard to get.

To remove them is a good thing. :-)

Not today though....

The tongue is good to test a 9V battery _ I can tell if they are good.
Havent done it on 240V tho.
Worst Ive got is 240V off a cartridge fuse

I was in someone else's shop one day and saw something falling off
the edge of the bench in my peripheral vision, and caught a hot
soldering iron. Luckily I had my tool box with me so I grabbed some
pure silicone grease and smeared it over the burns. I lost a layer of
dead skin a few days later, but it didn't dry out enough to crack and
bleed, which would have taken a lot longer to heal.

If you are considering a new vertical antenna, instead of guesswork
and copying somebody else's un-thought-out efforts, download program
RADIAL_3 from website below.

The program assists with choosing an economic length and number of
shallow-buried ground radials. It takes a new look at how radials work
by considering them to be lossy, single-wire transmission lines,
open-circuit at the other end.

RADIAL_3 is a self contained file, 55 kilibytes. Easy to use. No
training needed. Download in a few seconds and run immediately.

>

Andy comments,
John, your results would be more consistent, and more meaningful,
if you had some sort of ground plane in your experiments.

A wire, by itself, with nothing else, is like trying to light a lamp
with
only one prong plugged into the socket......

The radiating element, which you are measuring, has to have a
counterpoise (ground) to establish the Efield against and an Hfield
around.
In your setup, the housing of the MFJ, and your hand, and probly
other stuff, is the counterpoise, and the results are inconsistent.
I suspect that if you took a measurement, and started to pee on the
ground, the reading would change (grin).......Try it. But keep the
power low :>))))

So, while your experiments may give you an idea of what the
resonant frequency and impedance of a piece of wire is, unless you
are able to take consistent, repeatable measurements, you can be
sure that something is not being accounted for..... My suggestion
is that you need a good counterpoise...... Maybe buy a sheet of
corrugated tin from Home Depot, mount the connector in the middle,
with the MFJ on one side and the antenna wire on the other.... You'll
find, I am certain, that your readings will be more consistent.....

This is not a bad ground plane for 2 meters --- I have used one
with good results......

It ain't magic, but there isn't any such thing as a unipole
radiator....

Good luck,

Andy W4OAH

I believe that -- at least from a mathematical perspective -- "infinity" is a perfectly good counterpoise. (Just as isolated conductors have capacitance to infinity and inductors have "partial inductance" whereby a return path at infinity is assumed.)

As a practical matter, of course the user's hands and other objects in the environment will affect the measurement, but suggesting that "one must always have a well-defined counterpoise" would tend to discourage one from studying antennas that are less sensitive to counterpoises than those that are, and this endeavor is quite valuable for the design of miniature antennas. After all, there are millions of commercial devices in operation every day for which the counterpoise is ill-defined.

3779. Newbie Question: PC Based Oscilloscopes

I haven't touched RF test and measurement equipment for about 20 years. Back then I used a standard 50MHz dual trace scope. I want to get back into homebrewing, and was wondering whether anyone could advise me on buying PC based 'scopes. Do they have the same "look and feel" as a dedicated 'scope?

There appear to be many such PC based scopes (e.g. Vellman), I was wondering what homebrewers would advise, given the "average" budget (not 10,000 Dollars + !!). Something with a pretty good Spectrum Analyser built in?

Or would I be better off going to Ebay and buying an old dual trace scope for 100 Euros or so?

Advice anyone?

Andy comments:
Yes... well... maybe..

In order to propagate, the Poynting vector has to have an Efield and
an
H field. The E field is between the "wire" and it's
counterpoise....specified
in V/M .... that is the voltage between the two divided by the
distance
between them..... As an aside, the orientation of the Efield is the
polarization of the antenna --- vertical, circular, horizontal,
elliptical, etc....

Now, if the counterpoise was at infinity, the Efield must always be
zero,
since any voltage divided by infinity (to give V/M) will be zero.
Hence there
can be no propagation..... Like connecting up to one terminal of a
battery..

All antennae, even the very inefficient ones used in "commercial
devices",
have a hot side and a ground. If the ground is well defined, as in a
patch
antenna, the field and radiation characteristics are well defined. If

the
counterpoise is simply a ground track on the PC board, it is fairly
well
defined, but the radiation is, well, squirrelly. Fortunately, a
matching
circuit assures that power will be radiated, even if the field is not
pretty.

Loop antenna, which do not work against a ground plane, use one of
the two feed points as a counterpoise. Such antennas are easier to
visualize using H fields, tho, as before, one MUST have and E and an
H field for it to actually work.... The Efields of a loop exist
between
sections of the loop as a function of the current flow thru the loop,
and
don't give much of an intuitive feeling..... but I digress...

If you know of an antenna that has no counterpoise for the "hot"
side to
work against, please post some information about it..... However, in
my
experience, it would be like having a magnet with a North pole and no
South pole ---- ain't no such thing..... Yet, I'd be glad to learn
if you
would care to teach.....

Andy W4OAH

PS And I would be very interested if Roy LeWallen would step in here
with an opinion. He has done more antenna stuff than I have,
and
may be able to explain it better..... I know he hangs around
this
group since I have seen his posts . :>))))))

Andy writes:

I've used a couple of the systems that plug into the PC and use
software
loaded into it. It is mainly an A/D converter with several channels,
and
the software gives the user the versatility to establish timing, etc...
I MUCH MUCH MUCH prefer the old fashioned analog scopes, tho, since
I can fiddle with it and don't have to worry about aliasing, sample
rates, etc.
I suppose the latter software programs have all the user friendly stuff
built in, but, personaly, if I didn't write the program myself, I don't
know
where I would get into trouble applying it. I don't like to used
"canned"
"one program does all" stuff..... (unless I wrote it :>)))).

One really cheap system I used was, I think , BSOFT. I don't know
if
they are stillin business, but they sold a board that plugged into a PC
(desk size) and only cost 50 - 100 bucks. Worked up to several Mhz.
But that was 15 years ago -- everything is much faster now -- but you
have to pay for it.....

As I think about it, a big advantage for a PC scope is that the
measurements
are on a file somewhere, and if you have programming ability, you can
write an FFT, or a graph program, or, well, hell, almost anything

you
can think of ---- providing you can access the data file.... That
could be
a lot of fun.........

Good luck. But 50 mhz scopes are faily cheap now......

Where is the counterpoise on a handheld transceiver? I believe it is the
body of the transceiver, the hand, arm, and body of the operator, and the earth.

The data in this thread was in response to an earlier thread of the same
subject. That's why I added "-followup" to the subject for this thread.
Please read that thread originally posted on 7/7/2006 at 2:29PM. The
following will make more sense if you read that original thread.

If you assume the MFJ is the body of a handheld transmitter, which it is,
then these results show how a quarter wave whip reacts to a handheld

transceiver having a metal enclosure. The counterpoise for a handheld is its metal chassis but usually separated from the operators hand by a plastic case.

In the original thread, there was posted links that are now broken (7/9/2006, 11:37AM). As I recall one of the items appeared to be a whip on a camera. I think the other one was a whip on a radio. So, I tried to make some measurements to show how much variation there can be with wire antennas and to underscore the fact that there is no way anyone can predict what a wire antenna's impedance will be on the objects the OP referred to under the myriad of conditions possible.

Cheers,
John

3783. could VFO frequency be below IF ?

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-07-19 07:54:44 UTC

Message-ID: <1153295684.841238.155880@i3g2000cwc.googlegroups.com>
Source record: 11184

hi,

I'm experimenting with my superhet. My IF is 8mhz (cause I have 8 mhz crystals for IF filter). I first experimented on 40m. VFO was 15mhz. At design time I'm using 3 meters long wire as an "antenna" (and I'm sitting in my basement). I heard different european stations (EA5FKX, RW6XE, UR4GI etc) which are several thousand km-s away. Pretty amazing for such "antenna"!

So I decided to go for 20m band. I had an option to set my VFO either to 6mhz or 22mhz. I first went with 6mhz. But for my disappointment I heard nothing but the band noise.

So I'm confused now - is it because the short "antenna" or am I wrong thinking that VFO 6mhz + IF 8mhz should give me 14mhz?

any ideas?

3784. Re: could VFO frequency be below IF ?

Source record: 11185

Yes.
It was often used in two band trx - with 9MHz IF and 5-5,5MHz VFO.
result was 80m and 20m without VFO switching.

****** Yes. If the case is conductive. Even if the case is metal ,
and not
connected to the internal "ground" , it becomes part of the
counterpoise
by capacitance. Of course, the hand is conductive, etc.....

So, I tried to make
> some measurements to show how much variation there can be with wire antennas
> and to underscore the fact that there is no way anyone can predict what a
> wire antenna's impedance will be on the objects the OP referred to under the

>
\
**** And you did that very effectively. I didn't realize that you were
trying
to show the significant variations, and thought you were wondering why
the readings were so different. Sorry,.... I just didn't get your
intent....

I would have liked to see what the piece of wire did with a nice ground
plane, tho, to see what the design baseline would have been.... In
other words,
a piece of wire looks like, say 32 ohms over a ground plane, but when
all the variables such as shape, no ground plane, people, nearby
objects,
etc come into play, it goes from hell to high water.....
I'm glad to see someone actually doing the experiments, rather than
just quoting a bunch of " E to the J Beta pitchforks" and letting it
go at that..... :>)))))

Alternatively you could use a ground plane of chicken wire mesh ,a bit
easier to handle than a sheet of metal.

Andy comments:
That's a good idea. I always seem to have some tin laying around
and
no chicken wire, but it would work well. Also hardware cloth -- that
stuff
with the little squares that is used a lot on rabbit cage bottoms.....

In fact, they would both be good for corner reflectors, with a PVC
frame...
Or a large bowtie dipole to get broadband at VHF........ hmmmmmmmm.

Thanks Frank, you have ALMOST inspired me to start another
project.......... maybe tomorrow :>)))))

I would also suggest that you get a mixer chart and get familiar
with
how to choose LO and IF frequencies for minimum spurious responses.
There is a mixer spur graph in Ref Data for Radio Engineers, and maybe
in the ARRL handbook.. Also , Minickts labs puts out spur response
charts for their popular mixers such as the SBL-1 and MD108 and it
shows which of the spurs are worst and allows you to adjust your
mixing frequencies accordingly.
The selection of a good frequency scheme is the STARTING point for
a receiver design. I know you are using stuff that you have on hand,
as all of us have done, but if you get familiar with frequency
management
you will be able to account for the signals you hear but don't know
why.....
It's usually due to spurious mixer responses....

Here's a couple rules of thumb, if you have NO OTHER WAY to get the
info you neet.

1) If the LO is either 9/10 of the received freq, (or 1.1 times
the
received freq for top side injection,), most spurs are low
response.

2) If the LO is near .25 , .50 or .75 the channel freq,
spurs are really bad.

3) The image response is equal to the desired ---- use front end
filtering.
(assuming you don't use an image regect mixer)

4) The "half-IF" response 2LO+/-2RF = IF , is really bad,
always.....
Use front end filtering to get it down also...

Example: RF 7mhz LO 15 mhz Half IF is 11 mhz Image is
23 mhz

Those are just off the top of my head. The best deal is to pull out a
mixer
chart. Personally, I wrote a little BASIC program to go thru all the
combinations
up to the 10th harmonic and print out all the responses that occur in a

bandpass I could specify... it's easy to do and gives you exact
numbers......r
.... but the mixer graph can get you in the ball park quickly.......

You might want to check how much RF your PC is leaking first.

Also check to see if the software can be run directly off a CD
without installing anything on your HD. My PC has enough
to do already. I prefer a dedicated time-based oscilloscope.
RF spectrum analyzers are expensive cupholders, nice to have
but ... well, if someone gave one to me for free I wouldn't complain.

That frequency combination will work fine. I once homebrewed a 40 meter SSB rig using a 9 MHz crystal IF filter and a 2 MHz oscillator and it worked fine. As a rule, the lower the oscillator frequency, the more stable it will be. Your 6 MHz will be far more stable than 22 MHz.

What everyone else said, plus:

Yes, a mixer should work on both sum and difference frequencies, so an LO that's lower than the IF is just fine for receiving a good strong signal.

You leave yourself open to more spurious reception problems. When folks are talking about 'spurs' and 'mixer charts' they mean you need to watch out for funky combinations of harmonics of LO and RF signals mixing down to your IF -- having the LO frequency higher than the RF frequency tends to reduce this problem. You can do this by hand by assuming that you'll be mixing 6, 12, 18, 24, etc., with 14, 28, 42, etc., and seeing if any of the combinations boils down to an IF of 8. If they do you could have spurious mixing problems, particularly if they're not high harmonics.

How about a half-wave antenna (end-fed zepp)? Assuming it's being fed by coax, would you suggest the counterpoise is the ring making up the shield of the coax right where the coax stops and the antenna starts?

I would like to hear from someone like Roy as well, since I certainly am well outside of any areas of significant experience here.

> rates, etc.

A *good* digitial scope will contain an anti-alias filter and sufficient smarts that you genereally shouldn't have to worry about these issues -- if you were to take a new Tektronix or Agilent DSO (or at least the "mid-grade" or higher "trim levels" -- the ones that show properly shaded waveforms to indicate how much time signals spend at various levels), I'm willing to bet you'd be just as happy as with your old analog scope.

Not that there's anything wrong with the old analog scopes. :-)

One of the main problems with inexpensive PC-based oscilloscopes is the fact that the specs are often considerably "low end" but often not presented in a way that makes this apparent. I honestly believe that some people think that hooking an analog signal directly to the input of, say, a 100Msps ADC somehow makes a "100MHz scope." :-(

Here's a nice comparison from cleverscope -- people who do seem to know what they're doing -- that compares various PC-based scopes:
http://www.cleverscope.com/resources/Cleverscope%20Comparison%20chart.pdf

Analog scopes are good when the human eye can perceive the trace adequately. Digital scopes are best with waveforms that are either too slow or too fast (and non-repetitive).

Each has its place.

Hi,

My luck (quite some time ago) with FETs was not nice either. Someone may have to correct my, yet the only way I think one can get away with fiddling with the things the way most people construct, might be to use zener diodes between the gate and source and drain. Once its all together and apparently functioning one probably could remove them then with less worry about then getting a little static jolt and ruining the junction. Tubes are a lot more forgiving.

Sincerely,

Gregory D. MELLOTT

***** One volt with respect to what other point ??

The RF generator
which drives the antenna has TWO terminals. If one terminal is
connected
to the wire, or the sphere, the OTHER terminal must be connected to
something else for the antenna to radiate. Hence, one terminal is
connected
to one side of the antenna, balanced or unbalanced, and the other
terminal is connected to either the other side of a balanced antenna,
or
some other structure such as a ground plane or counterpoise......
Remember, all RF generators are TWO terminal devices, and the
voltage is the voltage between the two terminals, not between one
terminal and some other point located on Mars.......
This potential difference sets up an Electric field, and the attendant
electron motion sets up an H field, and thus an energy wave
propagates.......

The coax or balanced line is not the radiating system the though it
may interact some it's the matching network from the low (under
600ohm) to high (>3000ohm) impedence at end of the halfwave

antenna.

Coax can be used but since one end is mismatched from it's
characteristic impedence it could be lossy. Usually it's not as the
matching section is small (~1/4 wave). In practice it works very
well and there are antennas like Spertof (sp??) and other coaxial
fed antennas are very succcessful.

The frequency schemes should work fine. Be sure you don't have a high pass filter somewhere between your vfo and your mixer. I don't know what kind of mixer you are using but if it is an active mixer then there could easily be some kind of filter involved. That's why I like diode ring mixers with resistive pads between the vfo and the mixer - it gives you a good termination for both the mixer and the vfo and there isn't nearly as much to worry about.

I hear ya about tubes being more forgiving, much more fun, too.

Just wish they didn't have such weird power requirements.

Actually, maybe the soldering DID do it. Are you using an iron with a three prong cord? The third prong ties the soldering iron tip to ground (assuming that, if so, you are plugging that into a GROUNDED three prong outlet and not using one of those three prong to two prong adapters). Also, this is assuming you are in the United States...not sure about other countries outlet wiring.

Jamie,

Go to http://www.kitsandparts.com and use the toroid calculator he has there.

Another thing you can try is wrapping 25 or 30 turns and then measuring it with an LC meter in the L mode of course. AADE sells a fantastic LC meter kit for about $100 - I built one a few years ago and I use it every week when digging in the junk box looking for caps and coils.

Good luck with your regen, have fun.

25 Turns of #28 on a T50-2 is about 3.2 uH not 300 mH

23 Turns of #28 on a T50-2 is about 2.6 uH

T50-2 has a AL of about 49

uH = (AL * TurnsSQR) / 10000

So...

(49 * 625) / 10000 = 3.065 uH (25 turns) for 2 - 30 Mhz

(49 * 529)/ 10000 = 2.592 uH (23 Turns) for 2-30Mhz

3806. Microwave oven transformers

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-07-21 12:42:50 UTC
From: AndyS <andysharpe@juno.com>
Message-ID: <1153485770.076247.315190@s13g2000cwa.googlegroups.com>
Source record: 11107

Andy writes:

I have been thinking about building a high voltage power supply
for a big amp, and am toying with the idea of using a couple of
microwave oven transformers, which I have on hand.

I plan to use two, with the primaries connected in parallel but
opposing, so that each one will supply voltage, half-wave, to a
diode ring. By doing this, I can have each core grounded like it
is used in the ovens....

So, has anyone else done this and run into any problems that
I may not have forseen ?

Thanks,
Andy

Drew VK3XU had an article in AR magazine recently about this - he used 2 of them, the primaries in series, the secondaries in //. He removed the magnetic shunts. With effectively half supply on each one, they didnt go into saturation but maintained full output voltag. He lifted the ground wire of the secondaries to frame - this was supposed to be a big no no, but his experiments showed there was no breakdown to earth, he then used a bridge rectifier on the resultant // secondaries...got good results,.....

Andrew VK3BFA.

I soldered fets with a max V gate to source of 10 volts with no prob.
The trick is to wrap the leads together with some bare 30 guage and
then after soldering remove the 30 guage.
Use a grounded iron and set the pcb on a sheet of aluminum foil with
470k - 1 meg to ground
the resistor is to save you if you touch something leaky and the foil
at the same time - like a bad scope or something.

Using 1/2 wave rectification on each one will result in big DC currents
in the coils. These DC currents will saturate your cores like nothing else.

If you wanted to do this and be safe you'd want to rewind the primaries
after insulating the core with some appropriate high-dielectric strength
material like Kapton.

If you're in the US you may want to consider using the primaries in
series, and running off of 220V.

3812. Input circuit for grounded grid amplifier with 2x 813

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-07-22 15:39:03 UTC
From: df9gr@darc.de
Message-ID: <1153582743.878289.81760@p79g2000cwp.googlegroups.com>
Source record: 11113

Hello,
I got a pretty old amplifier with 2x 813 tubes in grounded grid. I runs nicely with 700 to 850 watts from 80 to 10m. I already did some modifications (vacuum relays, fan control, 9 band operation (80-10m) and now I am looking for some ideas for an input circuit. I meassured the input impedance of the tubes with about 120 to 130 Ohms which gives a bad SWR on a 50 Ohm output stage of a modern transceiver. I also tried a 1:4 UNUN. Results where slightly better but the SWR is still to high. As I want to avoid to use of an external tuner I am looking for someone out there who has build an input circuit (e.g. 1 collins pi-filter for every band) and can give me some advice how to calculate or build.

Hey, Tim -

IIRC, there is only one diode attached to the transformer in my microwave.
That would mean it is half-wave rectified as it comes from the factory. Yes?

Cheers,
John

Thanks for your comments, Andy. I agree with you on experiments. There are
times, however, I would rather experiment using EZNEC than with the MFJ. It

all depends on circumstances. One method can be faster than the other depending on the goal.

In fact, it has been between 105 and 108 degrees here for the last week or two, putting a crimp in outside activities. I would rather stay inside and model my unusual thoughts than to try them outside. On the other hand, I don't know how to model an MFJ enclosure, my hand, my body, and such in EZNEC. So, that is when I measure.

Also, there are times when both methods are warranted. Like, measure to determine if your model is correct. Or, model to determine if your test set-up is correct.

Each method has its advantages and disadvantages. I just hope I have the knowledge to choose the appropriate method when it comes time to do the work.

73,
John

Source record: 11117
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.homebrew,rec.radio.shortwave

Those with an interest in building a Wellbrook ALA 100 setup for use on an antenna rotator may want to check out my most recent blog entry (July 22nd). I have pictures and construction details that describe the way I approached the project.

I believe the ALA 100 is the most flexible and useful Wellbrook model for the do-it-yourselfer. You can construct the loop in whatever manner suits your abilities and requirements.

My use of the ALA 100 is primarily for DXing foreign medium wave signals, with a secondary use of hearing third-world broadcasters on the tropical bands. I've heard of some amateur radio operators using Wellbrook antennas for a receive-only solution, too.

Yes, come to think of it -- yes. Perhaps the core is sized to take it.

I guess the next question is how much harder can you push the system if
you _aren't_ putting DC on the core?

If resistive I always figured anything under 3:1 was good.
I've fed a pair of 813s in GG at close to the legal limit with a
fairly modern transceiver with good results, but I never checked to
see what I had for an input impedance. I guess that was one of those
cases where ignorance is bliss <:-)) I didn't know it was high so I
didn't worry about it.

For input impedance matching, look at a schematic of the Henry 2K4.
They use a separate matching network plugged into an octal socket for
each band. The ratios are different, but the design could easily be
modified and the layout is easy to experiment with. I don't have the
manual handy, but as I recall it's just an adjustable transformer with
a tap.

I think you'll be able to find the whole manual at BAMA

Do they not put a capacitor in series with the transformer secondary, and
then connect this combination to a diode in parallel with the magnetron?
In this way the capacitor would prevent DC in the transformer.

No. Its actually a full wave voltage doubler - the tube itself is used
as a diode.
And there not, strictly speaking, "proper" power transformers - a
saturable reactor would be a better description. They use this to
current limit the things cheaply - notice the big "Boing" when they
switch, noticeable on a low duty defrost cycle.

73 de VK3BFA.

PS - as a self employed electronics technician, working alone, I refuse
to work on the things in my business - too many people been lethally
zapped by them, and no one nearby to give CPR......

I did mention the spiral configuration to him, but he didn't comment on it.
The construction seemed to be easier, so it's the only style I considered
from the start.

There is a company that makes a controller for some of the commercial
GE radios that have been around for several years. They allow control by
computer or at a distance of about 100 feet from the control head using a
standard computer microphone. Does anyone know the name of the company.

I am interested in finding them and one or two of the radios so that I can
play around a little bit.

Thanks in advance.

Yes I have done a search in Google.

I read an article years ago on using them for powering linear amps --
the first thing you were supposed to do was knock the shunt out of the
core. Apparently this is usually quite easy unless it's spot welded, in
which case it's quite hard.

> 73 de VK3BFA.
>

This could be wise -- once you broach the case on one of those things
you're into voltages that will deal instant death. But that's the case
for just about any tube linear amplifier.

Spiral concentric or coil will change the pattern but since the antenna
is so electrically small it won't make much difference unless you want
to use the nulls. I would expect that a coil wound would be best. I you
are concerned about using a null in the antenna pattern then go one turn.

Not true.

A network with an inductive input will allow a square waveform at the device output but not waste significant energy in harmonics. I've done that in designs.

In the 1950's RCA had an AM BC transmitter that drove a tube with a near square wave, and had a near square wave. The RCA transmitter used a low-mu triode that had parallel tuned circuits in the grid and anode set at the third harmonic. It had conventional networks feeding the grid and to the antenna from the plate resonantor. That transmitter made over 95% anode efficiency.

And the point is that the Class-C only conducts on a portion of
that sinewave anyway, requiring that tuned circuit in the output
as a "flywheel" in order for there to be a sinewave at the output.
The "harmonics" are a byproduct of that non-linear conduction
at the input. And of course, that's why an amplifier could easily
become a multiplier simply by tuning the output to a harmonic of
the input signal.

3832. Biasing of Dual Gate Fets

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-07-25 05:32:40 UTC
From: David <websales@orbitcoms.com>
Message-ID: <Y1ixg.272$rP1.237@news-server.bigpond.net.au>
Source record: 11133

Hi,

Pretty fundamental I know but can someone please explain the steps for setting up bias for a Dual Gate MOSFET.

I know I could place a pot on the gate and source for each circuit and play with values but I would like a method that enables me to calculate the values.

The main issue is how to determine values for Rs and Gate 2 Voltage.

I am using BF998 and want to have a "play" at 5V and 8V supply.

The formulae for Id is Id = Idss(1-Vgs/Vp) ^ 2
But Idss is stated as 2-18mA
Vp Gate 1 is given as a range from 1-2V
Vp gate 2 is given as range from 0.5 to 1.5V

If I apply say 4V to G1 and 0V to G2, how do I calculate the voltage at the source to determine Vgs ?

Any help much appreciated.

Regards

David

The point is Reg said a square wave would decrease efficiency and a
sine wave was just as good, but that really isn't true at all.

Don,

Thanks for the link to Wes's experiments with MOSFETS.

It still does not explain how to calculate the current or anything about datasheet specs.

I understand some may be curious about what I might build. Typically it will be MOSFET amplifiers. My interest at present is the basic fundamental calcualtions that should be applied to determine Gate voltage and Source resistance for a self-biased Dual Gate MOSFET.

If the calculations are the ones in my previous post then I need to know whether I use min or max values of IDss and Vp etc in the calculations.

There must be some straight forward calculation steps for biasing a Dual gate MOSFET. I can find literally hundreds of articles for BJTs but cannot find much on Dual Gate MOSFET bias.

I can see from the datasheets for example that best noise figure is when ID = 10mA. But cannot see how I calculate source resistance and Gate bias to end up with required VGS and ID. I don't want to pull out pots and play with VG2 and Rs combinations to find out what values set up the appropriate current.

Regards

David

One way of doing this is to get the datasheet for the FET you are using. There should be a graph that shows the operating characteristic curves. The x-axis will be Vds and the Y-axis will be the drain current Id. The characteristic curves will be for various levels of Vgs. Pick an operating point based on the type of amplifier you want. Let's suppose it will be Class A. Assume the FET has a power supply voltage of 40v and an Idss of 10ma. Let's say that you pick a point in the middle of the operating curves that gives an Id of 6ma and a Vds of 20v in order to get the maximum swing out of the amplifer. Looking at the characteristic curves shows that this will require a Vgs of about -1v. Now you have everything you need.

If Vgs needs to be -1v and Id is 6ma (assume Id and Is will be the same) you need a resistor of Vd/Id (R = V/I) or about 166 ohms.

The gate resistor you see in FET amps is not really there for biasing but more to set the input impedance of the amplifier. As long as the leakage current from the gate to the source is small, Vgs is set by the bias resistor in the source lead.

3840. Two Terminal Networks - Antenna Traps?

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-07-25 21:21:43 UTC
From: kl7r <kl7r@yahoo.com>
Message-ID: <1153862503.112228.132210@m79g2000cwm.googlegroups.com>
Source record: 11141

An Antenna trap is a parallel LC circuit that has one input
and one output terminal. You can make a resonant trap
with series LC that also has one in and one out..

Is it possible to make a two terminal network lowpass filter?

Something like a sharp rolloff RF choke?

Thanks
KL7R

3841. VXO tuning range vs load capacitance

Newsgroup: rec.radio.amateur.homebrew

I built two versions of a Colpitts VCO using red LEDs as varicaps.
Version one had too much load capacitance and the center frequency was
a few kHz below nominal. However, it had a fairly wide tuning range as
the LED was varied about 10p it would tune around 1kHz. A second version
had exactly the right base load capacitance (it oscillated within a few
Hz of 25MHz on powerup), but the tuning range using almost an identical
setup is much narrower.

Is this strong attraction to the natural Crystal frequency normal?

You must remember that parallel and series resonant circuits in
antennas are not really two terminal networks. There has to be ground,
common, earth or whatever and it is common to both the input and
output.
A lowpass filter is realized by a single inductor whose impedance
increases, with increasing frequency. Highpass with a capacitor-the
sharpness of the rolloff is dependent on the Q of the passive devices.
That is it in a nutshell.
There are other factors that enter into this if the devices are used
in antennas. There are several hundred posts to chose from on the
antenna forum.

If you're using a load capacitance you're not using the crystal's
natural resonance frequency -- that occurs at the series resonant frequency.

Were you using the same crystal for both circuits? The same LED?

I would try this out with a trimmer and parallel cap that mirrored the
expected range of the varicap, _then_ I'd add the extra variable of an
unknown varicap.

Point taken. It's a crystal cut for a parallel resonance with a specified
load capacitance (18p, I think).

> Were you using the same crystal for both circuits? The same LED?

Not physically the same parts, but identical parts purchased at the
same time.

That's an obvious idea I had totally overlooked!

3845. Re: Biasing of Dual Gate Fets

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-07-26 00:33:50 UTC
From: David <websales@orbitcoms.com>
Message-ID: <OLyxg.715$rP1.458@news-server.bigpond.net.au>
Source record: 11146

Tim,

Thanks for the info.

So, say I wanted to set the bias up at 10mA.

I find the Vd/Id curve on the datasheet.

If I have say a 8V power supply and decide to use a choke in the drain.
This gives me Vd of around 8V. The curve indicates that VGs1 should be
0V and VGs2 = 4V.

This means Rs would be 8/10mA = 800R.

Where I am now confused is that VGS voltages are the Gate to source
voltage. If the source voltage is 8V from the example above then to get
VGS2 of 4V then the bias on VG2 would need to be 12V ?
Also if VGs1 = 0V then the actual voltage on G1 should be 4V ?

Is this correct or am I misinterpreting something here ?

Thanks.

Regards

David

Source record: 11147

OK, I think I got it.

Let's say I want Vdd = 8V. Say I have an RF chock in the Drain then Vds
is almost 8V.

Say I want 5mA bias current.

I look at the Vds vs Id and find that VG1-s = -0.2V for this condition.
(So actual VDs is 7.8V)

Next I use a source resistor of VG1-s/ Id = 40 Ohms
As VG1 = VG1-s + VG1 - IDxRS the Gate voltage applied is 0V.

The graph on the datasheet mentions that this is the output when VG2-s
is 4V.

So now I calculate VG2 = VG2-s + ID x RS = 4.2V

I suppose that I can make Rs smaller to the point where VG1-s is 0V on
the graph.(Occurs at 10mA for BF998).

If I want higher Q point I then add positive bias to V1. I also
understand I can get around 10dB attenuation by lowering VG2-s from 4.2V
towards 0V but need to make it negative if I want to switch the signal
off altogether (If I was to use the FET as say a ASK or OOK modulator).

Thanks

I'm sorry, I should have picked up on the fact that you are using a
dual-gate mosfet.

A dual-gate mosfet is a lot like 2 fet's in series. Gate2 is usually used
with an external bias to set the dynamic range of the device. The signal is
usually associated with Gate1. You can apply a fixed bias to Gate2 or tie

in something like an AGC signal to vary the device amplification.

For this type of device you probably would be better off looking at the graph of the Transfer Characteristics. The graph will show the change in Id for changes in Vgs1 with Vgs2 at a fixed value.

For your device I would probably run Vgs2 at 3v to 4v. Looking at the transfer graph, you would want Vgs2 to be around 0.1v to get in the middle of the linear curve. That would put your standing Id at about 9-11 mA.

This would make your source resistor 0.1v/10mA = 10R.

Remember that you'll want to breadboard the circuit and try this out before actually including it in a production unit. Use a fixed voltage divider to get the 4v for Vgs2 and a source resistor of 10R and see how the circuit works. You can always change the source resistor to get what you need.

Source record: 11051

Tim,

Say we look at VG1s = 0.1V as per your example.

The graph for BF998 shows that if VG2s = 4V and VDs = 8V then ID approx = 12.5mA

This would mean that unless I applied a negative voltage on the source I would need to apply 0.1V forward bias to G1 and 4V to G2 ?
As Rs is creating a negative self bias voltage ?

If I set the bias point lower - say 5mA then VG1s is approx. -0.2V according to the graph.

I can achieve this by using a resistor in the source of 0.2/5mA (40 Ohms) and then set VG1 = 0 (so that VG1s = -0.2V) and then 4.2V on G2 so that VG2s = 4V.

Is this correct ?

The transfer characteristic curve shows that for say 10mA. If VG2s = 4V then gm = around 24mS and if VG2s is reduced to 0V the gm reduces to about 7mS.

Thanks

regards

David

The problem with using FETs of all kinds is the wide part-to-part variation. Look at the specs for the BF998 - many of the critical specs show only a maximum or minimum, but not both, or just a typical value. You can be way off if you simply use a "typical" set of curves. If you want to do an analytical design with a part with non-specifications like this is to use a curve tracer to generate curves for the individual part, then use those curves for your design. Pull another part of the same part number from your drawer, and you'll need a different design. This exercise is useful for educational purposes, but it isn't a technique you can use to design something that can be easily duplicated.

That's probably why you don't see a lot of FETs being used in commercial products, except in applications where there's a lot of feedback to stabilize the operating point, such as source followers, or when simply nothing else will do. Even then, the manufacturer has probably paid the vendor to select parts with a much narrower, and well specified, range of characteristic values. That's been my experience in designing commercial electronic test equipment.

What you say makes sense. Breadboard up a circuit and see what your idle point winds up being. That's really the only way you will find out for sure.

Roy,

So if I had an adjustment on VG2 for each circuit and adjust for
required Drain current on each product ?

What's the consensus regarding Common Base BJT as LNA ?

Thanks

Regards

David

Or pick a set of bogy values and accept there will be a range of
operating current.

I've found DGmosFET perfomance is not greatly impacted by
variations in Idss and Gm for practical circuits.

>What's the consensus regarding Common Base BJT as LNA ?

Hard matching the input at any decent current, at 4-5ma the input R
is around 5 ohms. Easily overloaded as a result of usually being used
at low current to make the match easier. It's feature is fair
stability and the device is working at at it's alpha cutoff frequency.
The latter was more important 30 years ago when UHF transistors
were harder to get. Noise performance was dependent on device
but even in 1972 I could get TIMX10s down to around 1.5DB at
450mhz.

Imagine a WalWart store going in across the block from a ham station
running EME on 2.4 Gig. I wonder what a strong discrete carrier would
do the integrity of the RFID system. They would certainly need to be
far better than the end user WiFi stuff being sold.

Sorry, I have almost no experience in using dual-gate MOSFETS, for the reasons I mentioned. Beginning somewhere around the mid-80s, when manufacturing became highly automated, my employers strongly discouraged designs which included any adjustments. Besides the labor required to make the adjustment, the variable component lowered the product's reliability, so we'd often design in a lot of parts to get around having any tweaks. But individual adjustment is still a viable option for some products. What I don't know is whether you'd get satisfactory performance with widely differing devices all running at the same drain current. That would depend on your design and application.

If you're considering making a product, I'd certainly do some modeling with extreme component parameters to see what happens. And you might consider some sort of device selection and/or incoming inspection or sorting to make sure you don't get any truly extreme parts. One thing to be careful about is that when a part is so poorly specified, other companies might be buying large numbers of selected parts. That leaves you with the leftovers. I've seen some really strange distributions resulting from this -- parts with extreme characteristics on both ends, but nothing anywhere near the "typical" values. It used to be common with zeners, until they got better at making -- 10% tolerance zeners would all be between 5 and 10% from nominal, in both directions, with none closer than 5%. Those had been selected out and sold as 5% tolerance parts.

Just a few of the things I've picked up in 30 or so years as a design engineer.

Hi all,

I have a Tek 495P S.A serial group B020000 with option 39.

I am looking for the user manual and if possible also the programming manual.

I have the 495P Service Manuals 1 & 2 for serial B031000. Hope these are more or less OK.

It is appreciated if the manuals can be in electronic form to download or on a CD.

Thanks for your help

Gian

I'm in the process of building a pair of 813s (GG) with microwave oven transformers. I have two of them, slightly different size and about 4% difference in secondary voltage for 115 primary. Both ovens had nameplate current specs of 15 amps, max, but the transformers look like intermittent duty. From the schematics on both ovens, the transformers had one side of HV sec grounded, so I'm going to use each transformer for half of each cycle into its own diode string. Then, a bunch of electrolytics in series with voltage divider/bleeders on each cap. I've actually had the half wave version going, putting out 1500 vdc onto the plates of the 813s, and the transformer I used did not hum at all (I had a variac on the primary and cranked up from zero and back down to zero). I don't know about the "magnetic shunt" that some of the other posters are talking about.

The schematics both showed the magnetron as in a circuit where it looked like the tube was conducting only on one half of each cycle (no diode rectifier, no filter caps). The filament circuit (filament winding was separate, and apparently only a few volts and maybe tenish or so amps judigin by the wire gauge). Stampings on one of the transformers makes it look like it has max 2.6 kv output, so I'll need to keep primary voltage lower to keep rectified DC output around 2400 v for the 813s.

3861. Re: Class C amps saturating?

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-07-30 00:32:47 UTC
From: WSQT <wsqtradio@ziplip.com>
Message-ID: <1154219566.980885.120930@m79g2000cwm.googlegroups.com>
Source record: 11064

This is what is meant by "Class F." A Class F amplifier has traps tuned to various harmonics to allow the use of a longer conduction angle and/or square wave drive with high efficiency and excellent modulation characteristics.

There is also Class E-with a SERIES tank that is an open circuit instead of a short to harmonics. These are run somewhat detuned so as to cause the circuit voltage to fall to zero at switchon and switchoff with square wave drive. 90% efficiency not uncommon with both E and F. I

There are still other such tunings such as "inverse F," where EVEN harmonics are blocked but odd shorted. This can be as simple as a push-pull circuit with no center tap in the output tank if the interelectrode capacitance is low enough at the lower harmonics, as it often is for an AM broadcast or a 160M ham amplifier. For higher frequencies this design requires parallel resonating the interelectrode capacitance at one or more even harmonics abd becomes pretty much a fixed-frequency affair as a result.

Inverse F(odd) is again capable of 90% plus efficiency.

All of these amps work by blocking the high harmonic current that flows when a square wave pulse of 180 degrees angle is fed to a normal tank circuit, which is essentially a short to harmonics. this allows the active device to turn on and off with essentially no extra resistance(from the device) beyond full-on in series with the load, for all of the conduction angle.

The resulting tunings effectively square off either voltage or current waveforms depending on the partucular tuning used. In other words, current or voltage in the tank is NOT a sine wave, but the portion that is trasferred to the load must be a sine wave or else filtered. In fact, Class F may have been invented when someone put a harmonic trap in a plate circuit to stop a nettlesome harmonic current from flowing and then being coupled out. That is in some old RAH editions as a desperate measure for stoppign harmonic TVI, but also allows more amp efficiency if part of the design.

Straight Class C is in fact also capable of 90% efficiency, but only with a very narrow conduction angle so the plate current pluse flows only when tank voltage is already very low. This requires high back bias, high drive-and a larger than normal tube or transistor. The "power density" sucks, and in fact Class B is capable of more power for a given maximum current and voltage, assuming the heat can be tolerated. Class E and F amps can match Class B power densities with

early(narrow-angle) Class C efficiency.

For a tube low power density means higher filament power, giving
back some of that efficiency. Going to flourescent lights in the
station may save as much electricity cheaper in that case.

from the ARRL newsletter:

==>FIRST ARRL ONLINE AUCTION PLANNED FOR OCTOBER

The ARRL may be giving eBay and the other auction sites a little competition in the Amateur Radio arena this fall when the first ARRL Online Auction gets under way. Auction proceeds will help to support the League's educational services and programs. The event now is in the planning stages, says ARRL Business Services Manager Deb Jahnke, K1DAJ.

"We will soon embark on an exciting new venture," Jahnke said in providing the broad strokes of the online auction to ARRL Headquarters staff members. Jahnke and her Business Services team will organize and manage the event, which is planned for late October -- the exact dates haven't been set yet -- and she promises it will be lots of fun.

"This will not be just another boring auction, because we plan to include many unique and special items related to Amateur Radio," she said. "We are hoping to offer items that will interest our audience, ranging from DXpedition vacation rentals to restored Collins 75A4s." Jahnke says this inaugural online auction will be limited to 100 items.

The auction will be open to all -- ARRL members and otherwise. Bidders just need online access to take part. "With an online auction, we can reach potential bidders across the nation and around the world," Jahnke pointed out.

Jahnke says she anticipates that the online auction will be open for about two weeks, and participants will need to register in advance. At this stage, she says, the auction planners are seeking additional ideas but no auction booty as yet. Contact Jahnke via e-mail <djahnke@arrl.org>.

FWIW, I found the following SPICE model for the BF998 on the web -- note that the two MOSFETs VMAX are dissimilar, a lot of the entries are for parasitic elements:

```
* BF998 SPICE MODEL OCTOBER 1993 PHILIPS SEMICONDUCTORS
* ENVELOPE SOT143
* 1.: SOURCE; 2.: DRAIN; 3.: GATE 2; 4.: GATE 1;
.SUBCKT BF998 1 2 3 4

Hi Bill,
thanks for the idea. I didn´t knew that there is something available.
I will check if I have the space available but I am afraid I have not.

Hello Roger,

thanks for information. I found the schematics of the 2K3 at BAMA (no
2K4) and I am currently downloading it. I will have a look on their
solution.

Try Vintage Manuals, <http://www.w7fg.com>. I recently ordered a manual
for my B&K function generator and was very pleased with the service.

3868. Re: Biasing of Dual Gate Fets

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-07-30 16:34:39 UTC
From: "William E. Sabin" <w.sabin@mchsi.com>
Message-ID: <zc5zg.1109151$xm3.327105@attbi_s21>
Source record: 11069

In ancient times I set up a VHF amplifier test circuit with a dual-gate 3NXXX and measured gain and IM distortion vs bias parameters, DC feedback and negative RF feedback. I was able to compare many samples and found that I could get adequate (for my purposes) uniformity for a dozen samples in a particular application. The tradeoff is reduced gain to get "improved" uniformity. Trying to get max results from a single stage is not as good as two or three cascaded more modest stages. The cost of this approach is of course not minimal. The first stage dominates total noise figure.

Except the Ham Station is a "Licensed Radio Service", which has Priority over any unlicensed system for the purposes of "Interference Problems", on ANY Frequency. Mr. WalWart wouldn't get two steps with the local FCC as his is an unlicensed or Part15 operation, and is specifically subject to, and must "accept" interference from a Licensed Radio Service, and must not cause interference to any Licensed Radio Service using the same frequency.

Me been there, Inspected that, shut down the unlicensed operation had the "Big Shot" complain to HQ..... got him NOWHERE....

>Roy Lewallen, W7EL

Roy,

There are a large number of VHF and HF radios both past and present
that use the DGmosfets in place like the RF amp sometimes a balanced
mixer. A recent example is the TenTec 526 (6n2) 6 and 2 meter radio
as the RF amp. Another current example is the TT 1208 transverter
also as RF amp. If your not pushing the device for max gain or
ultimate IP3 possible they perform well and offer low noise for their
power needs. Neither require pots or other tweaking (other than
tuneable circuits). Can other deivces be used to do better, yes.
But, engineering is always about understanding and compromize.

I'd never use DGfets for something like a scope amp or other instrumentation where DC operating point or balance is a requirement. I have use them as a high impedence (1mohm) AGC'd input for high input senstivity frequency counters. Another place where I've used them is IF amps, they are just far easier to AGC than CA3020 or MC1350 and quieter.

My favorite line from years back.

Good, Fast, Cheap, Pick any two.

Allison

WallMart has to comply with the FCC Rules and Regulations, just like
every other company in the USA. RFID or whatever makes no difference.
If you think otherwise, show where the FCC has done other than
enforce it's Rules on commercial, noncommercial, or unlicensed
operations. RFID is an unlicensed or Part15 Service, and therefor
MUST comply with the requirments of Part15, if it is used inside
the USA. As the rules stand today, this means that the RFID System
MUST accept interference from ANY Licensed Radio Service, and MUST
NOT cause unreasonable interference with ANY Licensed Radio Service.
If such an interference complaint from a Licensed Radio Service
Station was received by the FCC and it was subsquently investigated, the
Investigating Engineer or Inspector would, site the Part15 Rules
to the interfering source, work with them to eliminate the interference

and if not successful, require the interfering source to cease operation untill such time that the interference was eliminated during operation, at the Licensed Radio Service Station. It wouldn't matter if it was US Steel, WallMart, or IBM, the rules and enforcement would be the same. Rules are rules, and the Rule of Law is what stands here in the USA, and it applies to everyone, equally, Big Shot of little guy.....

Me if you can afford the airfare, come on down.....

Doesn't say much about their quality control if the devices are that
dissimilar.

FWIW, I have developed a semiconductor and tube curve tracer for use within
Multisim -- create the component in Multisim, plug it into the curve tracer,
run the test and compare with the manufacturer's charts.

I have also built a tube curve tracer -- same will apply for
semiconductors -- even published an article on it. With this i can compare
the characteristics of the device vis a vis mfr data sheet AND the
simulation in EWB.

Question: Does anybody know how to calculate the width of a 50 Ohm microstrip line on Arlon PTFE circuit board (Type GX-0065-45-11). It is 0.0065" thick, double sided and has a k=2.45. Looking at my chart, it looks like I leave the bottom as complete copper groundplane and take off all copper around stripline on the top side of the board and leave the stripline as 0.0195" wide? That doesn't sound very wide!!

.0065 is paper thin, possibly less.

1/16 inch is 0.063 -- did you slip a digit?

Ok Pollyana, let me spell it out for you:

1. You will begin transmitting a carrier on the RFID frequency as you previously stated.

2. WalMart will have their golf and drinking buddies in the FCC track you down. If necessary, WalMart will have a few senators and representatives nudge the FCC a little. In this case, "nudge" means "jump", as in "how high?".

3. The folks at the FCC will determine that you are causing deliberate interference, a very serious violation in their opinion.

4. Your license will be yanked.

5. You will take a second and third job to pay for lawyers to fight the bastards. You can't possibly earn enough so you go in debt to them as well.

6. You will lose anyway and now you will be in debt up to your ears.

7. You will find that being in debt to lawyers is especially not fun.

8. You will wish you had never heard of RFID.

9. You will wish you had listened to Uncle Bill when you had the chance.

And that's the truth.

It isn't very wide at all.

I've built stuff on 15 mil 5880, twice as thick as your
paper-thin material. And it was still a handful.

What are you building? Why so thin?

Nope...the stuff I have IS paper thin. Very flexible. Bought it to use on upper UHF and into the microwaves. I didn't measure it with a micrometer, but I will do that later and report back...

The reason I bought it was that there was a whole bunch of it available at the Central States VHF Society conference this past weekend. They did have some slightly thicker stuff and maybe I should've bought some of that as well. Oh well, I'm stuck with this, so I'll have to try to use it...it's for a homebrew 902 beacon using a few MAR-4 devices. I will have to measure the lead width on these devices, but they might just be about the same as my calculated stripline width of 0.0195". This would be a good thing, but I agree, it may be a bit challenging to make a strip that narrow on the board (a magnifying lens and a very sharp scalpel!)....

Class F, class X, class Y.

They are all recent "names" hung on what are really just class C amplifiers.

I can do the exactly the same thing without a so called "trap" so long as the output device sees a high impedance at the third harmonic or better yet at all off harmonics.

That isn't a trap anyway, it is a resonator. The function is to provide a high impedance at the third harmonic so the waveform slope is steep. It allows the output device to go through the transitional state where it is dissipating maximum power very fast. The goal is NOT to allow a longer conduction angle. The goal is to have the output device either on or off and spend less time in the high dissipation area where device resistance is neither very low or very high.

The ideal duty cycle is 50%, with half time totally off and half time in saturation.

This is why a very low mu trode with tons of negative bias worked so well for RCA. The grid and anode 3rd harmonic resonators allowed the grid and anode to see a very high impedance at the third harmonic, and this sped the transition time up.

Tom says,

> The ideal duty cycle is 50%, with half time totally off and half

> in saturation.

==========
But 50% off and 50% on corresponds to Class-B bias conditions.

This is inconsistent with "tons of negative bias".

All that's required is a plate load which allows a square-wave plate voltage waveform during the "on" period of the operating cycle. (A very wide bandpass filter circuit configuration sounds appropriate).

Subject to this condition, a less than 50-50% operating cycle probably does provide, somwhere, maximum efficiency.

I like your lumping together of Class-C, F, X, Y amplifiers.

Reg.

I know you already have the material, but for such a
low frequency and non-critical application I'd use plain
old 1/16" G-10 pc board. YMMV.

Mini-Circuits have an excellent on-line catalogue
(http://www.minicircuits.com), and the lead width
of a MAR-4 is indeed .02 inches. This seems small,
but I'm at work and all my MMICs are at home... :-)

If the dielectric material is 6.5 mils thick and the copper is very thin, the width needs to be 18.7 mils. If the substrate material is 0.0065 inches thick and the copper is "one ounce" (1.4 mils thick), the width needs to be 17.3 mils. If the total thickness is 6.5 mils, and that thickness includes top and bottom layers of "one ounce" copper (leaving 3.7 mils of dielectric), the thickness needs to be 9.5 mils.

Good luck!

None of the above, could even happen, UNLESS the CongressCritters
passed a Statute and it was signed by the President, to have the FCC
CHANGE it's Rules on Part15 Devices, which by the way would take a MAJOR
amount of time, as all these Rule Changes would be subject to NPRM
Requirements of Part2 and the Federal CFR Publication Process.

Your senerio is BULLSHIT, and you wouldn't know the "Truth" if it
bit you on your Prompus ASS.

Ok SmartGuy, can you SHOW anywhere in FCC Records or Documents, where
the Commission acted in violation of it's own PUBLISHED Rules, in ANY
way similar to your above, BULLSHIT Senerio?

No? Really, Hmmmm, wonder why that is?
Must be your just full of it........

and just for your information, Field Operations doesn't work that way...
Investigations don't happen, like your dillusional senerio.....
Any good Communications Lawyer would blow the FCC out of the water,
should they act contrary to there own PUBLISHED Rules, in any Federal
District Court in the Land, should it ever get that far, and the FCC
Legal Counsel knows that, and would never allow the Commission to get
themselves in that situation, in the first place.......

Where do you come up with this stuff..... Nightmares R US......

Me

Well, I read through the ARRL's FCC Rulebook last night, looking at
their definitions concerning interference and use of frequencies. The
FCC Part 97 regulations never use the word "deliberate" with regard to
interference at all! They use the words "willfully or maliciously",
which are similar but not quite the same.

I think Bill's scenario (which assumes a significant amount of political collusion) is somewhat overblown, at least to the extent that I can't see any evidence in the records that any case such as he suggests has ever actually been prosecuted by the FCC.

On the other hand, this fact doesn't mean that an amateur operation who deliberately set out to knock out Wal-Mart's Part 15 system would not be subject to (legitimate) discipline under the current FCC rules.

As I see it, there are several issues here. One issue is that of "who has authorization to use these frequencies, under what conditions, for what purposes, with what protections?".

On that basis, the use of (e.g.) certain 2.4-gig frequencies by an amateur radio operator, for legitimate amateur-radio communications purposes "within the rules", certainly trumps any Part 15 applications.

The ham is not, however, allowed to just run wild on the airways. The ham must comply with the FCC rules. Among the rules which appear relevant in this case:

97.101 (d) No amateur operator shall willfully or maliciously interfere with or cause interference to any radio communication or signal.

This is clearly a question of intent, not of effect. If your intent in transmitting is to interfere with "any radio communication" - if you're transmitting only for the purpose of jamming someone - then you're breaking the rules and can be disciplined. On the other hand, if the interference is a side effect of your otherwise-legitimate transmissions on a band for which you have primary privileges, and the interfered-with party is a Part 15 user who "must accept any interference", then as far as I can see you're not obligated to either shut down or take action to mitigate the interference.

97.313 (a) An amateur station must use the minimum transmitter power necessary to carry out the desired communications.

Simply blasting away with 1500 watts to reach somebody across town wouldn't be reasonable. On the other hand, 1500 watts in an EME setup would probably be reasonable, as long as the antenna system and beam shape don't expose anyone to excessively high levels of RF.

So, I think it's likely to come down to the ham's being able to show that his/her transmissions are part of a legitimate process of communication with one or more other hams (i.e. that they are not _intended_ to cause interference) and are otherwise in compliance with the FCC regs and good amateur-radio and engineering practices. If this is the case, the FCC is unlikely to be able to show good cause to take action against the ham.

On the other hand, if a ham is simply keying up and transmitting a high-power carrier, for no reason tied to any actual legitimate amateur-radio purpose (communication, technical study,

experimentation, etc.), then the question of the ham's intent in doing so would arise, and the ham might be charged with "wilfully or maliciously" interfering with other radio communications.

Now, the FCC *could* choose to invoke 97.27, which allows them to modify a station grant and place restrictions on it (e.g. limits on operating hours, frequencies, modes, transmitter power). Such modification-of-grant rules seem to have been put into place back in the early years of television, in order to enable the FCC to restrict some TVI-causing ham stations during prime television-watching hours. The rule requires that the FCC determine :

(1) That such action will promote the public interest, convenience, and necessity; or
(2) That such action will promote fuller compliance with the provisions of the Communications Act of 1934, as amended, or of any treaty ratified by the United States.

The FCC has to make determination, issue a modification order in writing, and give the ham 30 days to protest the modification, before the terms of the modification can take effect.

It'd be interesting to see whether the FCC were willing to go on record (in public and in writing) in an assertion that unclogging Wal-Mart's Part 15 RFID system was necessary to promote the *public* interest, convenience, and/or necessity.

---------- REPLY SEPARATOR ----------

Certainly I can. And you can too if you like.

For example, try getting the FCC to shut down a 500 KV power transmission line because it's interfering with your ham radio communications. This has been tried and the FCC's response is "That would not be in the public interest". This actually happened.

A clear violation of the rules, but he who makes the rules can also violate the rules.

And the word is spelled "scenario", DumbGuy.

Some years ago I used Visio at work for schematic drawing, but I no longer have access to it. Can someone recommend a program to use at home for creating schematic drawings? I don't care if it is payware as long as the price is reasonable. I found a couple with Google which were several hundred bucks, a bit much for my needs.

Do recent Visio releases still have schematic drawing capability? I went to the Microsoft website and they advertise all kinds of drawing capabilities, but not schematics.

Thanks in advance,

Bill, W6WRT

Switchercad III is free spice software with schematic capture.

Try Kicad
Its a capable OSS program that will run on Linux or Windows
(I use it on Linux - havent tried M$)
has a project manager to allow PCB drafting from the schematic

Well lets look at the case sited. 500KV Powerline is not in and of it
self a Licensed User. Their emmissions come under Part15, and what
"Proof" was submitted to the FCC that the PowerLine was the cause?
Power Companies, in general, are required to maintain their systems
so as to eliminate emissions, when they interfere with Licensed Radio
Services. They are required to replace insulators that are bearking
down and flashing over causing radiated emissions. These type of
issues are handled by the FCC every day, and I have PERSONALLY dealt
with this type of regulatory issue, many times, just like the neighbors
Fish Tank Heater causing Pink Noise from 10Khz on up to 25Mhz. There are
Case Files where the Commission has levied fines to Power Companies for
not replacing failed Insulators that caused MF/HF Interference. One of
the best ones, I remember, was a regional Power Company was issued a
$10K Notice of Forfiture for repeated failure to eliminate interference
from a line that passed a USCG MF/HF CommSta, after repeated Notices of
Violation. The CEO was named in the Notice, Personally, and he was given
10 days to reply, and if he didn't the Federal Marshal would be knocking
on his door, with a Warrent, signed by the local US District Attorny.
That got the CEO's attention and the insulators were repaired in
quick time. No more interference. USCG Base Commanders bloodpressure
returned to normal, and his mumbled threat to shoot every bad insulator,
was completly forgotten.
Billyboy, you seem to have issues with Federal Regulators that go far
beyond the scope of this news group. They have medication, that is
helpful in such situations. Have you looked into this for your Health?

Any good CADD program can do that. If it is the symbols your looking
for, most of the good CADD outfits have libraries of Electronic,
Electric, Mechanical, and Structural Symbols, or you can build your own
library of symbols.

Most of the time I see RF stages coupled with .1u caps, which are
basically transparent at RF. Sometimes I see very small values
used, like 3-10p.

A couple examples are in:

http://www.amqrp.org/kits/38spcl/schematic.html

C17 (near the middle top, connecting U2 to a tank) and then the output
of that tank to U4A (unmarked, but also 5p).

It's clearly important to the circuit (empirically) but I don't understand
what they're doing. I can sort of see C20 (the unmarked second one) acting
as a high-pass RC filter.

Those small capacitors effect an impedance transformation into and out
of the tank. They also reduce the shunt R seen by the tank, which
increases its loaded Q and therefore selectivity.

Here's an open source prog that works pretty well.
http://tinycad.sourceforge.net/
It makes nice schematics and is pretty easy to use.

Depends on the frequency and the impedences.

>A couple examples are in:
>
> http://www.amqrp.org/kits/38spcl/schematic.html
>
>C17 (near the middle top, connecting U2 to a tank) and then the output

>
>It's clearly important to the circuit (empirically) but I don't understand
>what they're doing.

It's part of the matching network, the upper cap is the 5p and the
lower is 100p. Also by making the value small the amount of RF
coupled is lower (capacitive attenuator) along with tuning L2.
It is a simple circuit but has a more complex analysis.

For example U2 on recieve is a product detector and the desired
output from pin 4 is audio. On transmit it's used as a mixer to get
the VXO and BFO to produce a ~10mhz rf signal at pin 4. So making
the path for RF use a smaller value to keep any audio out of the path
is part of the circuit "tricks".

Since the design makes many of the parts serve dual duty
the analysis is often less than obvious.

>I can sort of see C20 (the unmarked second one) acting
>as a high-pass RC filter.

It's doing two jobs, DC blocking and a somewhat high pass coupling.
However the impedence at that point is fairly high so coupling values
can be smaller. The device there is not an opamp but a inverter
(digital logic) from a CMOS IC pressed into service as an amplifier
so there are some things done arount it to make behave are as needed
to make it work.

Ben,

The series C17 coupling cap is working against the net reactance of the C19-TC2-L2 circuit to form a resonant impedance matching network. Although it's not obvious, the tank network is tuned on the inductive side of resonance in order to produce exactly enough net inductive reactance to resonate C17. At this setting, C17 and the net inductive reactance of the C19-TC2-L2 network form a series resonant circuit. Because the whole network is resonant, the junction of C17 and the C19-TC2-L2 network is a higher impedance point than the pin 8 output of U2. Assuming lossless components, energy must be conserved, and so the signal voltage at this high impedance point is higher than at pin 8 - yes, voltage gain in a passive network! The unmarked coupling cap feeding into U4A is probably just a large value "DC block", since the U4A stage design will have a fairly high input impedance and so will not substantially load the tuned impedance step-up network.

Most people think that couping caps are just used to drop signal voltage sort of like inserting a resistor, but if designed carefully as part of a resonant interface as I described, they transfer energy with little or no power loss, and can actually produce voltage gain. This is a very important RF design concept that many folks don't understand.

That was my assumption, however when I replicated that part of the
circuit, I found that when U4 was at 8V, the signal picked up a LOT
of phase noise. I'm assuming that the 10k feedback resistor that
biases the inverter for linear operation was back-driving the tank.
Or perhaps it's the fact that in the inverting amplifier configuration
the XC of C20 is required to set the gain at a reasonable ~3x instead
of essentially infinite. In that case I should have been able to
use a .1u + 3k R for the same effect.

Anyway, I've found this tiny bit of circuitry to be very informative!

Hi all,

I am looking for some more Tektronix manuals. A local friend was
supposed to get these for me but his friend sold the gear and manuals
long time ago.

TR 503 Tracking Generator used associated with Spectrum Analyzer TEK
496, I will use it with the 495P.

DM501 Digital Multi-meter. I have a short circuit somewhere internally
so I need mainly the circuit diagrams.

Thanks for helping me.

Source record: 11032

I have 4-5 boxes of unused surplus Philips Ferroxcube 4BI (or 4B1) Ferrite RF Chokes. These are basically just a multi-aperture core with a piece of 24 Awg Bus wire threaded through it. They work quite well for supplying DC bias for low to medium power RF devices in the VHF and UHF frequency ranges. Each box supposedly contains 1000 pcs. but there's probably a few missing. (I'm not going to sit here all day and count them!) I figured one of you guys might be able to find a use for these. They're yours if you pay for shipping costs from 91732 (near Los Angeles.)
Here's pictures:

A cheap tracking device can be purchased through one of the following pages.
http://tech-software.net/index.php?module=pagemaster&PAGE_user_op=view_page&PAGE_id=5&MMN_position=7:7
http://www.silcom.com/~pelican2/PicoDopp/PICODOPP.htm
I really don't think tracking devices have to be expensive but if you don't like paying for a good one, then I can provide a very simple 555ic timer circuit you can use that will cost about $10 to make.
Here is the circuit of a very simple but workable tracking device that I once used to track a signal to tandy's store in the toowong towers in Brisbane. Once you learn how to use it, you can track to a square metre. A hand held radio is the best choice of radio to use with the tracker. This shop blocked ch 7 for 3 days until I had some free time to go and see where it was coming from. The same shop did it again some time later and the culprit lost his job at that location thanks to a night time worker that was on the ball. The signal was a radio on the shelf connected to power with a small antenna and a clip lead over the mic insert to hold it on tx.

3935. FS: Very rare National MB-40-L

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-08-08 19:23:15 UTC
From: Wes Stewart <n7ws*@*yahoo.com>
Message-ID: <54phd2lbkbe87gg62fg0ihn0vg432mljkg@4ax.com>
Source record: 11036

I'm not getting any younger and it's time to clean out the stuff
that's not going to get used anytime soon.

This is a National multi-band tank circuit that tunes 80-10 meters
with one turn of the shaft, without a bandswitch. Ideal for tuning
the input of that big linear, incorporating into a low-power antenna
tuner or whatever.

I believe these were originally rated for 10 watts, but I think it
should handle more than that from the looks of it.

Photo at: http://www.k6mhe.com/n7ws/MB-40-L.jpg

Asking $50 and I'll pay the shipping in CONUS.

Email n7ws@yahoo.com

73,

Wes

3936. FS: National R175A Plate Choke

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-08-08 20:20:16 UTC
From: Wes Stewart <n7ws*@*yahoo.com>
Message-ID: <c5shd2h7uciib4pa8hlm6scirsssa8m324@4ax.com>
Source record: 11037
Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.swap

I have two new, unused, National R175A plate chokes (radio frequency chokes) for sale.

These are ideal for high-power tube type amplifiers. They are wound in sections on ceramic forms to avoid resonances in the amateur bands.

Photo at: http://www.k6mhe.com/n7ws/R175A.jpg

Asking $25 each, or $40 the pair, shipped CONUS.

email n7ws@yahoo.com

73,

Wes

3937. FS: B & W 850A Plate tank assembly.

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-08-08 21:18:56 UTC
From: Wes Stewart <n7ws*@*yahoo.com>
Message-ID: <0kvhd2d061s887s9s0s84fqrtbfb0jd4l8@4ax.com>
Source record: 11038
Cross-posted to: rec.radio.swap,rec.radio.amateur.homebrew,rec.radio.amateur.equipment

For sale one B&W (Barker and Willimson) 10-80 meter plate
inductor/bandswitch assembly.

This is the big one for that BIG amp you want to build. This item is
used but as new. Shiny silver, perfect ceramic and no arcing on the
contacts.

Photo at: http://www.k6mhe.com/n7ws/850A.jpg

Asking $200 shipped to CONUS.

email:n7ws@yahoo.com

Source record: 11040

Are you building an amplifier from scratch? If so, I recommend using "brick" RF modules. They are so simple...just mount them on a heatsink, wire up a couple of voltages, feed them with the proper input RF level (usually in the 1-200 mW range) and take the output from the module and run it through a low pass filter to the antenna. See http://www.rfparts.com/module.html for available modules and frequency ranges. They have many modules for the range you seek. Most modules listed have data sheets at that site as well.

> But 50% off and 50% on corresponds to Class-B bias conditions.
>
> This is inconsistent with "tons of negative bias".

You are right. That was a mistake. It can't be a 50% duty cycle when
the PA has very high bias.

But the waveform can be very square and the efficiency up near 100%.

Thats a possible solution.
But sincethis is homebrew, does anyone sell a power transistor or IC that
goes to 450MHz/900MHz?

Absolutely! RF Parts Company (the one I originally gave you) sell
discrete transistors as well as tons of parts. I don't know why you
wouldn't want to use an RF modules as all the impedance matching is
already done for you for the most part...the device input is 50 Ohms and
so is the output. Very minimal designing needed to make a functional amp...

Just a quick note to add to my previous replies....

http://www.rfparts.com carries a boatload of transistors, a few examples
such as:

RD30HUF1, 520 Mhz, 12.5V, Power out 30W $24.70
RD60HUF, 520 MHz, 12.5V, Power out 45W $29.20
RD45HMF1, 900 MHz, 12.5V, Power out 30W $32.90

Here's a list of many others:

http://www.rfparts.com/transistorspecs.html

If you know exactly what you're doing, you can design and
build a UHF amplifier from discrete components. If you know
exactly what you're doing you can make it stable and linear.
But if you knew exactly what you were doing you wouldn't
need to ask USENET which transistors to use.

Everybody else uses bricks. They work.

You don't give the guy much credit for wanting to learn, do you?

I agree that someone asking for the transistor number itself isn't likely to be ready to *use* it for the intended purpose, but everyone has to start somewhere, and looking at the data sheet for parts you've insured are actually available certainly isn't the worst spot for someone wanting to build their own PA. Additionally, the problem becomes simpler if the OP doesn't need much linearity because he's only interested in FM.

> Everybody else uses bricks. They work.

I've blown up plenty of bricks due to improper termination... :-)

The old Motorola data books (bipolar and mos) used to have a bunch of app
notes showing reference designs for various frequency ranges. Perhaps one
can scrounge those, or find them on the web.

I glanced at one of the latest Freescale data sheets. It gave the test
circuit's microstrip dimensions, but not, alas, a board layout. None
the less, those dimensions should get you part way there.

Nice older 2-meter multimode. CW, USB, LSB, AM and FM transceiver.
Min. 10W output. I've used this rig with external amps to run meteor
and tropo scatter and EME.

Been keeping it to get back on EME but health issues are preventing
the construction of new antenna.

Asking $225 including shipping to CONUS.

email:n7ws@yahoo.com

Thanks and 73,

Wes

Ms Halliday,

I've worked with microwave transistors, striplines, Smith Charts,S-
parameters,etc back in the 90's. I don't exactly see a whole lot of
transistors still made for power applications at these frequencies.
We weren't allowed to use bricks in those days. It was sort of like using
a calculator to do basic arithmetic in school.

I shudder at the price of those old obsolete transistors.

3951. AM Stereo/FM Stereo Receiver

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-08-11 07:40:30 UTC
From: ungvichian <ungvichian@thaimail.com>

I would like to be able to build, from scratch, an radio receiver for AM Stereo and FM Stereo. I only have a rough idea of what I need (I DO need a C-QUAM for example, a MC13028), and I have next to no experience with electronics (just an electronics lab class, and some education on computer-programmed boards, during university), so I have no idea where to start (although I would be able to solder the thing together once I knew what I had to do). I do know, however, what I want in my theoretical receiver: a small size that I can carry around, 2 speakers for stereo output, knob tuning like a regular analog dial radio (i.e., with a small arrow on a horizontal dial pointing out the frequency), and possibly the ability to run off batteries or mains (220V 50Hz) as well as a jack for outputting to headphones (or a computer for airchecking purposes ;)). And of course, no old-fashioned tech like tubes ;).

I know Chris Cuff has been known to make them, but who knows where he's been these last few years? (Okay, he did have a few reviews at Amazon as late as last year... and I just emailed him a few hours ago, but who knows if he still checks his inbox?) Besides, I've seen his radios at sites on AM Stereo, and the tuning he uses doesn't exactly lend well to sensitive tuning (with the frequencies written right on the knob).

Come on, help me out here.

I think that was her implicit point. A brick is simpler and probably
less costly than building a discrete amplifier. Plus, we're past the
90s now and bricks seem to be the way things are going. I'm not even
sure if any of the major manufacturers are using discretes anymore (on
6M and up, that is). Maybe Ten Tec is...but all of the VHF and up stuff
I've bought in the last 10 years or so is brick based.

There's a pretty daunting undertaking for someone with your background. Are you looking just to *buid* such a receiver or do you want to learn how to *design* such things and understand exactly how they're working?

What's your budget look like?

You might want to start with something like http://www.esssales.com/elenco/radio-kit.html and then start hacking the IFs to go to your stereo decoders.

> I know Chris Cuff has been known to make them, but who knows where he's
> been these last few years? (Okay, he did have a few reviews at Amazon
> as late as last year... and I just emailed him a few hours ago, but who
> knows if he still checks his inbox?)

My impression has been that (1) Chris has probably just gotten busy with the rest of his life over the past few years and (2) he's probably gotten everything he ever wanted to out of C-QUAM. He was still selling PCBs on eBay a few months ago -- I seem to recall reading that he said the response was so great he was going to get more PCBs made (his initial auction was for clearing out the last boards he had).

> Besides, I've seen his radios at
> sites on AM Stereo, and the tuning he uses doesn't exactly lend well to
> sensitive tuning (with the frequencies written right on the knob).

I think you're confusing "sensitivity" with "precision." If you're looking for precision tuning, unless you want to spend a lot of money, you should just get a PLL-tuner radio. As for sensitivity, as with FM stereo, AM stereo was

really intended to work only when large signals (well, SNRs) were present, and therefore Chris's add-on boards never needed to worry about sensitivity too much.

I think you're pursuing a worthwhile project here (you'll learn a lot in the process), but if you're looking to do something a little more up-to-date you might consider doing an AM/FM stereo with a low-power DSP for the stereo decoding. No MC13028 ICs, no FM decoders, etc. -- just digitize at IF and do the rest digitally. You might buy a cheap commercial AM/FM stereo like the old Sony SRF-42 (shows up on eBay regularly, and usually the prices are sane) and then compare the performance of the DSP-based implementation with the analog implementation. (The cool thing about decoding C-QUAM in analog is that you have to build an analog divider -- definitely not the kind of circuit you see every day!)

I didn't even see this type listed at RF Parts...the original poster was looking for something that would put out 25 or 30 Watts (if I recall). What is the MRF511 capable of? Looking at the leads, it looks more like a low level amplifier...

3957. Voltage Calibration

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-08-12 21:00:45 UTC
From: joegeller@gmail.com
Message-ID: <1155416445.535052.122950@p79g2000cwp.googlegroups.com>
Source record: 10958

Some time back, there was a discussion of voltage references. The post is now in the public domain forever, so I feel a need to reply. Unfortunately I only saw it recently so I wasn't able to comment at the time. There is an incorrect statement regarding one of our products.

Early in the development of our most inexpensive transfer standard we did loan a board to an amateur. He compared it to his Fluke 731B and observed a change in reference voltage with temperature. He now offers his "spread sheet" in public asserting in this forum that our reference boards do not perform as advertised: >>"If you can duplicate his temperature you will do pretty good but probably not quite as good as he advertises."

Our inexpensive "SVR" boards are essentially high quality support boards for the AD587 reference chips. The specs. (including temperature coefficient) are largely determined by the specs. of the reference chip itself. Then it is important not to further degrade that tempco when adding trim resistors. Also, for the purposes of a trimmed transfer standard there should be a sufficient trim vernier to trim to a desired resolution without losing precision.

Early in the development of this board, we used AD587JN or LN reference chips with a temperature coefficient of 20 ppm / c (JN) or 10 ppm / c (LN). For a 10 Volt chip, 1 part per million (1 ppm) is one millionth of 10 V or 10 uV. Therefore an AD587 KN based reference can move by up to 100 uV per degree Centigrade and still be perfectly "within specification" (10 ppm over 1 degree c is 10 * 10 uV or 100 uV).

We now use the AD587 LN grade reference chip rated at 5 ppm / c. We have also improved the tempcos of the trim resistors, now using precision IRC 0.1% metal film resistors (for the reduced tempco, not the precision and note that the tempco of the trim resistors is not 1:1 because of the OpAmp circuit in the reference chip).

It should also be noted that most reference chips change reference voltage with time; usually this appears in a specification sheet as ppm / 1,000 hours. For example the AD587 series is spec'd at 15 ppm in the first 1,000 hours of operation. This is one of the reasons that we advertise this product as a transfer reference.

Our inexpensive "SVR" boards http://www.gellerlabs.com/SVR%20M.html are rated at 5 ppm / c and do that well or better. The previous post suggesting that our products do not meet advertised specification was an incorrect statement. We set the reference on our calibration bench to a resolution of 10 uV and record the temperature. We conservatively advertise a lower "transfer accuracy: Calibration data will be reported

to 10 uV resolution (.0001%). The last digit of resolution will only be useful in the short term at the reported temperature and power supply voltage (15V). Under these conditions, it is possible to obtain short term transfer accuracy of better than +/- .0005% absolute. The AD587 can move 15 ppm during the first 1,000 hours. The temperature coefficient is 5 ppm / C or better as limited by the AD587LN."

The previous poster's assertion that this specification is not obtainable is without merit and incorrect. We have never compared our SVR boards to a Fluke 731 that initially cost $5,000 and has now enhanced stability with typically 10 to 30 years of run time. Our boards can however be very useful to check the absolute voltage as a transfer standard with minimal attention paid to ambient temperature and good test practices.

Interesting find.

The latest transistors are LDMOS for UHF to lower GHz and FET GaAs PHEMT
for cell phones.

Interestingly enough, in Jim Williams's book "The Art and Science of
Analog Circuit Design", there's a chapter by Steve Roach of Tektronix,
which shows the use of a BF996 consumer-grade dual gate FET in a 1GHz
oscilloscope preamp.

I frequently see postings in the ham radio related newsgroups for items currently being offered on E-Bay.

All to often I that items will be shipped only to the lower 48 states, leaving hams in Hawaii, Alaska, and Canada out of the picture. What is the problem. In Canada we are well served by FEDEX and the United States Postal Service. Amateur radio equipment crosses the border with out any problem. I realize that Hawaii and Alaska may be a bit far from the "lower 48" but the same delivery services are available even though surface transportation may be a little bit slow. In the US you also have UPS, the folks in Brown which we Canadians prefer not to use because the often make the border crossing more difficult than it needs to be and we don't like getting stuck with brokerage fees.

So why the discrimination, if the buyer knows that delivery may take a little longer and is prepared to accept the fact then it becomes a non problem. If the seller is intimidated by the prospect of complicated paperwork, he needn't be. Please leave it up to the buyer to decide whether he wants to bib or not.

I can not speak for shipments to Europe, Africa, India, China, or the South Pacific but for fellow Americans, or friendly northern neighbours, I think that people should be prepared to deal with us.

Thanx for letting get this off my chest and I realize that I have cross posted this to four different newsgroups but I wanted to get to a broad audience.

Paul

Don't feel too bad, Paul. You'll often notice in the same listings that
(even if they ship solely by USPS) they will not ship to US military APO/FPO
addresses, either. We get left out in the cold even more often than any of
the above named locations. So much for supporting the troops as it were.--

USPS Air to South Africa takes 4 days from California. Customs is handled by them and it is extremely easy to use. Great service.

Americocentric sellers maybe?

Hi,

There is an occasional problem importing items here to the UK
from the States. Although the current GBP to US Dollar exchange
rate makes prices quite attractive, the postage often charged
doesn't. Recently I was quoted $64 on a single $19 integrated
circuit. The reason for this being that the supplier would only
send items overseas by what amounts to a courier services and not
by the good old US Mail. I think this is because they are tied in
to contracts with certain companies to handle their outgoings and
cannot deviate from them. Perhaps it is also this that limits some
of them to the lower 48. The postal service on the other hand may
absorb part of the cost in delivering items to Hawaii and the like
whereas the private companies may not.

Cheers - Joe

Hmmm???

Hawaii is too hot?

Canada is too big?

Alaska is just right!!

But this doesn't respond to the hypothesis.

That's because shipping to an an APO/FPO is no longer a service provided by the U.S. government. At one time mail to an APO/FPO was delivered to a U.S. millitary post office that then shipped it using U.S. milltary transport, There was a good chance that the mail would actually arrive and it would be undamaged. Now APO/FPO mail is sent via the regular postal system, but the U.S. government picks up the tab.

Now, the chance of the mail arriving is much less as it stands out.

As for Paul's comments, they really don't hold any water. Small sellers don't ship outside the continental U.S. because they don't want the risk.

If an item is lost, stolen, damaged, or takes a month or two to get delivered, they can't afford to replace it, or "eat" the loss. Paul even has more problems because Canadian customs may hold an item to determine its value, or if it can be legally imported as long as they wish. They can also assess the value for sales and other taxes.

Obviously he never has had any experience clearing an item through customs. If he had he would have praised the low fees, speedy processing and general reliablity of the courier services.

Considering the general quality of things sold on eBay, the sellers are actually doing you a favor. While many of the sellers will attempt to keep you satisfied, if you have to wait a month for something to arrive and in Paul's case pay GST (general sales tax), import duty and customs clearing fees, then have to send it back, he would loose a lot.

Besides paying for shipping both ways, he would have to pay customs clearing fees at the U.S. border and prove that the item he is sending back was actually being returned to the U.S. as a defective purchase and not scamming the customs people by claiming it was.

This means that some items both of you either have to keep or pay for and never get no matter what it costs. Where do you draw the line? $100, $200, $500? If it costs $100 to ship a radio to you and $100 to send it back, it does not make much sense.

Geoff.

Been here six years, and have NEVER had anything shipped to me USPS that
hasn't gotten here, and if it was properly packed, it has always gotten here
in one piece. I pay for Priority Mail shipping, which now is only a dollar
or two more than Parcel, and I get it here in a week to 10 days.

And actually, the USPS takes our mail as far as San Francisco via regular
channels, and from there it's shipped commercial air (just like any other
air mail) to our local APO hub, and then to the mail rooms.

With personal contacts in the USA it is often best to get the goods
(small bits and pieces)sent to a US address first , from where people
will then send it abroad.
The referred US$64 transportation cost will then be largely reduced.

The only possible problem is loss or damage. USPS air delivers in a few
days and for a reasonable border fee, most of which is sales tax at this
end. If the customs declaration is made out properly, stating that the
contents are amateur radio equipment and if the eBay auction price is
stated as the value, there is rarely any problem unless the merchandise
is misrepresented in the first place. There is no duty on amateur
equipment entering Canada from ANYWHERE, just sales taxes.

>
> The only possible problem is loss or damage. USPS air delivers in a few
> days and for a reasonable border fee, most of which is sales tax at this

The issue is cost, I believe.

For some reason sellers dont want to pay the cost to the last two
states, EVEN IF THE BUYER IS FRONTING THE FEES> DOnt know why.

I have shipped to Hawaii several times with no issues at all other than
time.

I have had no problems with Canada, other than time. Sometimes it
takes an inordinate amount of time . But you can accept that if BOTH
parties are good communicators.
>
Keep in touch with your seller or buyer, dont just fail to respond. It
makes them nervous, folks.

Source record: 10979

Andy writes:

I have lusted after an HQ180 for 50 years. And now I
might go out and buy one with my next Social Security
check....

So, how many here have experience with the 180 ??
I understand the 170 is more stable and a better receiver...
Anyone care to comment on this....???

I don't ham much anymore, but if I get a Hammarlund
I want to know what I might have to modify to get it working
well.... Anyone with experience in stabilizing/rebuilding/repair
on these Hammarlund models might like to talk about their
experiences, and I would like to listen...

I had an HQ170 in the late 50s. It drifted a quite a bit and also suffered from tunable hum. At the time, I lived in an apartment in New York on West 34th Street and Hammarlund was in a building directly across the street. The company I was with did some work for Hammarlund, so I knew several of the engineers. They were aware of the problem with the HQ170 L.O. So they decided to offer a mod kit, but did not want to go through the hassle of writing detailed instructions. They figured an experienced ham should be able to modify the circuit from the "before and after" schematics.

Since I had been a ham since 1939 and was a graduate engineer to boot, they gave me the kit of parts and told me to let them know if just the parts kit and schematics would suffice. I got it done, but it took about a dozen phone calls to their project engineer. Needless to say, they abandond the idea of selling such a kit.

I assume that the later production runs of the receiver incorporated the changes, but I do not know for certain.

3982. New Picture Gallery Additions on Elecraft Site

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-08-15 21:02:27 UTC
From: "Eric Swartz - WA6HHQ, Elecraft" <eric@elecraft.com>
Message-ID: <ebtcgi02tgt@enews4.newsguy.com>
Source record: 10984

We have just updated our Elecraft Picture Gallery with a super group of new customer pictures.

The pictures include custom machined paddles for the KX1 by WB9LPU, homebrew SO2R control boxes, SOTA mountain toping, FYBO KX1 Pics and K2 based DXpeditions to VK9X, VK9C, St. Martin, Key West, 8R1 and a host of other locations. Also check out our two featured pictures, including one of the newly discovered 'Cafe K2' in Sweeden. :-)

They reached via the 'Picture Gallery' link on the upper right side of the main page at http://www.elecraft.com

Special thanks to picture submitters: DL2KCD, DF4KV, DL3KMS, DL3ALX, DL7KCM, DL8BAG, SM7KJH, WB9LPU, DL1JET, K1EV, 6Y5/KN5G, 8R1ZUM (K7ZUM), DG2KAL, OE3ZK, DG8KAD (and bird), KD0RC, DL7JF, F5VJC (GM3SKN), KF6C, K1JD, KI4DGH, KT5X , K7TQ, KA3IXF, HB9AFI, N6IZ, N8XE, NY9H, PA3VBT, T32QS (N6TQS), W1TF, W6IZT, WA5KPA, WA7CS, SM5CBC, WH7N, W0YG (VK9CG, VK9XG) and DL2DE.

Great stuff guys! Thanks again for sending these pictures in to us.

I recently recieved three packages, one from the US via FEDEX GROUND,
another from the US via USPS, and another from Canada via Canada Post.
They all arrived in less than a week, and I paid no customs. There are
no customs duties for ham radio equipment.

Paul

3987. Add money to your Paypal account with OPRAH TS5Vi

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-08-15 22:52:43 UTC
From: NSI <af.irani@afyhpami.com>
Message-ID: <JUyEg.57516$vj1.6722@bignews5.bellsouth.net>
Source record: 10995

Read this message until the end, and you will find out how the money flows in easy !!!!.
Follow the steps and it WILL work. Trust me !!!!!.

It's NOT illegal and it is NOT a scam !!!!!.

PROVEN ON OPRAH! Reported in the Wall Street Journal!!!!

The only thing you need is : - E-MAIL ACCOUNT
- PREMIER (FREE) or BUSINESS PAYPAL ACCOUNT
- $6 on this account (The only investment)
- 30 minutes of your time

There is no limit on how much money you can recieve, and you haven't got anything to lose with this Business program. I will explain how it works !!!!!.

Follow these 4 easy steps and it WILL work !!!!!.

STEP 1 : SIGN UP FOR A FREE PAYPAL ACCOUNT !!!!!.

Paypal is a free and safe way to pay and receive money on the Internet.
Creating a account is as easy as creating a MSN account.
Copy and paste the next line in your Internet browser and sign up.
HTTP://WWW.PAYPAL.COM

Be sure to sign up for a FREE Premier or Business account and not for a Personal account. You cannot receive CREDITCARD payments with a Personal account and we can't have that. Do we !!!!!.

STEP 2 : SENT $6 TO YOUR PAYPAL ACCOUNT

This is your only investment to receive the money with ease.

With your Paypal account, send $1 to each e-mailadres listed below.
!!!!! IMPORTANT !!!!! Be sure to use this SUBJECT : *PLEASE PUT ME ON YOUR EMAIL LIST* when you send the money.

1) martine@pilote.net
2) dexxatol@netcourrier.com
3) armygirl8568@hotmail.com
4) comjii@starband.net
5) sinnek@bellsouth.net
6) nsi@nelasat.com

STEP 3 : PUT YOUR E-MAIL ADDRESS ON THE BOTTOM OF THE LIST

After you have send $1 to each e-mail address, put your e-mail address on the 6th place.
Remove e-mail address number 1, and move each e-mail address 1 step up the ladder.
!!!!! IMPORTANT !!!!! BE SURE THAT THE E-MAIL ADDRESS YOU USE IS THE SAME AS YOU USED TO SIGN UP AT PAYPAL.

Remember that this is LEGAL. You are creating a service : an e-mail servicelist.

STEP 4 : UPLOAD OR COPY THIS MESSAGE TO NEWSGROUPS, FORUMS ETC AND EMAIL IT TO ALL YOUR FRIENDS!

There are 32,000 newsgroups. Upload or copy this message to at least 200 newsgroups or forums etc, but ..... remember that the more your upload the more people will see your message and the MORE MONEY WILL FLOW IN.

How to upload to newsgroups and forums? :

After you have followed step 1,2,3 and 4, save this message (and copy so you can use it again).
Use your Internet browser and Outlook Express or another newsreader and try to find FORUMS, NEWSGROUPS,
BULLETIN BOARDS, DISCUSSION GROUPS, CHAT SITES and ONLINE COMMUNITIES. Use GOOGLE or use a NEWSERVER.
Use every option to post this message. Download PostXpert to send 1 message to more NEWSGROUPS at the
same time.

!!!!! REMEMBER !!!!! The more you post this message the more MONEY WILL FLOW IN.

Why does this Business program work so well !!!!!.

Lets asume that from the 200 (or more) messages that you have posted, only 5 people respond, you will have your
$6 back that you have invested. Those 5 people will each send at least 200 messages with your e-mailadres on
number 4. That's 6 x 6 x $1 = $36. The next 25 people will also send 200 messages with your adres on number 3. That's 36 x 6 x $1 = $216. The next 216 people also send 200 messages with your name on number 2. That's 216 x 6
x $1 = $1296!. Those 1296 people again also send 200 messages with your name on number 1. That will give us a total of 1296 x 6 x $1 = $7,776.

Now the last tier! 7776 x 6 x $1 = $46,656!!!!!!

This is only a EXAMPLE with 6 reactions. You WILL get MORE responses than that.

Remember that most newsservers will leave the posted messages on there servers for about 2 weeks. If you will post your message again, it WILL again start from the beginning. So you can repeat this over and over again.

Everyday MILLIONS of people are ONLINE and reading these messages, JUST LIKE YOU RIGHT NOW. I also was sceptical in the beginning and have read a lot of these messages. I also thought that it was bullshit.
Until I thought : What the hell!, only $6. What's $6 and a couple of minutes of my time to solve my money problems.

!!!!! REMEMBER !!!!! Follow every step, and IT WILL WORK, TRUST ME. !!!!!

!!!!! BEST WISHES AND GOOD LUCK !!!!!

w)O>+;)<9UVS;F>qaGL<Uq#v`V6(F]- rM;$g+!4IIQ*827?H4

Several years ago I had a pack and ship business. one of my customers had a VCR he wanted mailed to his son some where in Alaska. The post office used a contract air carrier to deliver the mail to the island where the son lived. As the package with the VCR was being off loaded from the seaplane it was dropped overboard. It took over a month to receive payment from the USPS (he did insure the package).

As for canada, there is a problem with tracking. At least a couple of
years ago, the cost of tracking a package, when possible, was
horrendously high. In the case of the US mail or Fedex, it was
impossible. I shipped to canada and the buyer said he didn't get it.
He sent a very impolite letter the day I noticed all other items
shipped that day arrived. I know he received it and later admitted
that it was shipped to the wrong address, which I know better.

Not being able to track makes for a risk that I was unwilling to handle at the time, so I cut out shipping to canada.

As for hawaii and alaska, tracking and shipping costs were terrible to those places as well. Some items can't be shipped by air and would be shipped by ship requiring a time delay in which, again, thieves take advantage of and get their refund.

The combination of eBay and Paypal creates a haven for thieves in those areas and others. They favor the buyer and it will ultimately cost the seller more in the long run.

APO and FPO can't be tracked either. Tracking is a requirement for the eBay/paypal so-called protection.

I was once a gi. Gi's move. Sometimes it takes a long while for the gi to receive mail that has to follow him/her.

I realize that the problems are caused by the 'few', but they create a risk or null out certain protective clauses in contracts. SOme businesses can afford to go through the extra effort, wait the extra time or live with the occasional loss. A business that loses one sale in a hundred can afford the loss better than an individual who stands to lose one in the only one or two sales they make.

Ebay/paypal is too protective for the buyers and not the sellers. The law is too difficult to motivate for most of the little sales that originate from ebay. Thieves know this and take advantage of this at every opportunity they can.

>costs to Hawaii/Pr/Alaska etc I give them the deep six.
> Joe

But the costs are extra to those businesses. shipping to those
states/territories are higher than cross-continent shipping.

Only a month? Not bad, really. USPS is notoriously slow with insurance claims (but then, aren't they all?)

The tracking is not a problem, FEDEX tracking works across the borders
and the USPS and Canada Post tracking systems interface with each other
using the tracking number issued at the point of mailing.

This comming Sunday...

+++ Now even more Buyers Parking !!!
Thanks to Shire we have use of their new parking lot
across Albany St from the SWAPFEST !!!

!! ** More Buyers PARKING is available ** for details see
http://web.mit.edu/w1gsl/Public/flyer

*** !!!! In our Traditional GARAGE and the adjacent lot !!!! ****
so come rain or shine or super heat the Flea is on !!!

********* $1 buyers discount with hardcopy of this notice ********

COMPUTERS - ELECTRONICS - HAM RADIO - COMPUTERS - ELECTRONICS - HAM RADIO

FLEA all SUMMER at MIT
Sunday August 20th 2006
9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take
place on the third Sunday of each month this summer,
April thru October.

There is tailgate space for over 600 sellers and
free, off-street parking for >2000 cars!

Buyers admission is $5 (you get $1 off if
you're lucky enough to have a copy of our ad)
and sellers spaces are $20 for the first and
$15 for each additional at the gate.

The flea will be held at the corner of Albany and
Main streets in Cambridge; right in the Kendall
Square area from 9AM to 2PM, with sellers set-up
time starting at 7AM.

SEASON PASS + Advance Seller Discount

A sellers discount season pass is available which
offers a 30% discount. By prepaying you get a
discount and earlier admission. See the registration form.

*** Attention Sellers ***
Prepaid vendors.. Season Pass or monthly,

will be admitted FIRST.
Separate lines will form prior to gate opening
for prepaid and nonprepaid vendors

!! RAIN or SHINE !! Have no fear of rain, a covered
well illuminated tailgate area is available for all
sellers (6'8" clearance).

Talk-in: 145.23- (PL 88.5) W1BOS/R and
W1XM/R-449.725/444.725 (PL 114.8/2A).

I've bought one of the Ramsey kits which should arrive this week.
http://www.ramseyelectronics.com/cgi-bin/commerce.exe?preadd=action&key=DDF1
I'll let you guys know how well it works when it's assembled.
Tracking to within a couple of houses is easy even without a radio that has
a signal meter but the doppler will make it all that much faster.
the serial ratbags and spastics in Sydney will get a fright when its up and
running. Unfortunately Sydney repeaters are going through one of those
phases where every sub-moron with a radio is having an obsessive compulsive
episode and we have about 20 whispering retards making the repeater
unusable. Hopefully within the next 4 weeks I can post an excel spreadsheet
with all their info. they usually piss off when they lose their anonymity.

Mark, Just ignore them.

They only tease you because of the stupid things you say when you
follow up. Just ignore them and they'll give up.

Stop giving them reasons to tease you. It only makes you look
more stupid.

Take a break from the radio groups for a while, Maybe work on your
moon bounce some more.

The HQ-170 only covered the ham bands of the time. The HQ-180 was
general coverage. Otherwise the two were rather similar.

yea, don't believe FedEx when they say they deliver to Alaska....They
only deliver to Anchortown, Fairbanks, and Juneau..... for all the bush
villages and towns, FedEx gets turned over to the USPS in Anchorage
for delivery, and there is NO Tracking after that..... FedEx SUCKS
for Alaska delivery..... Lost a Laptop to there system, no refund,
or claim was ever paid. got a letter from the Manager saying,
"So Sorry for your loss, I feel your pain." I'd like to give him
a bit of my pain, right in the ***........

4015. AGC signal/noise question...

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-08-17 20:34:27 UTC
From: Andrea Baldoni <abaldoni@nospam.invalid>
Message-ID: <X-WdnZl4X9xOT3nZRVnyuA@kpnqwest.it>
Source record: 10916

Hello.
I'm wondering about a thing...

When the AGC reduces the gain of an amplifier, composed by FETs (DG or SG)
or BJT, the SNR remains constant?

Or the performance of the amplifier may degrade/upgrade?

I'm researching about the matter and I just read that, in a BJT for instance,
emitter current is inversely proportional to the noise. So, if AGC reduces
the gain (so current), SNR degrade?

The question arises from a thing I just noted with a HF receiver... disabling
AGC reduces (slightly) the noise (at least in FM reception)...
Maybe just be a side effect, like noisy gain control signal...

Ciao,
AB

Mark, Just ignore them.

They only tease you because of the stupid things you say when you
follow up. Just ignore them and they'll give up.

Stop giving them reasons to tease you. It only makes you look
more stupid.

Take a break from the radio groups for a while, Maybe work on your
moon bounce some more.

Hi Andy, I owned a Hammarlund HQ-180 and I thought it was fabulous! I used it primarily for AM broadcast DXing. It would tune stations my ham HF rigs had a hard time picking out, even with DSP and filters etc. It was great on the sidebands in the ham allocations, and SWL was a joy. I sold it to make room for a HF ham rig. I kick myself for selling it, now that I have a shack that is big enough for it and my other radio toys. I never had mine alligned or re-capped because I didn't think it was needed. It performed very well. I used it more often than my Racal RA- 6790GM and my Collins R-388URR and they were both sold before the Hammarlund went. If I ever find another good condition one I will grab it, no questions asked! 73, Mike...w1sox > Andy writes:

Maybe, maybe not...

>I'm researching about the matter and I just read that, in a BJT for instance,
>emitter current is inversely proportional to the noise. So, if AGC reduces
>the gain (so current), SNR degrade?

Not necessarily true. Noise, true natural noise, in a bipolar
junction transistor is dependent on MANY things besides the
emitter current. Foremost of all is the source impedance
of the BJT's driving source: SNR will increase on both sides
of the measured least-SNR current in some transistors. If you
look at the characteristics/datasheet information on several
hundred different transistors you will begin to get the idea
of how many factors go into noise generation within the
transistor. :-)

Most complex Gilbert-cell ICs (Motorola MC1590, MC1350 as
examples) will control gain by "stealing" current of a
differential-input, common-emitter stage. While the example
ICs can control gain over a 60 db dynamic range, the worst
noise generated inside those bipolar-transistor architecture
ICs occurs at minimum gain control input (maximum
amplification).

At higher and higher input signal levels, there would be more
AGC control action but the SNR would also be higher and higher.

>The question arises from a thing I just noted with a HF receiver... disabling
>AGC reduces (slightly) the noise (at least in FM reception)...

There isn't much FM on HF. What there is would be in
narrow-band Data mode signals. Some of that Data is a
combination of AM and PM similar to a wireline modem's
modulation.

Disabling the AGC would put the overall gain of the receiver
at maximum. Naturally there would APPEAR to be "more noise"
since the receiver would be picking up ALL noise available at
the antenna input.

>Maybe just be a side effect, like noisy gain control signal...

That's also possible, but unlikely there in my opinion.

What is needed in an investigation of this is a reasonably-
well-calibrated signal generator with a calibrated attenuator.
On AM you could simply increase the signal generator output
until the total signal plus noise reaches a certain level at
the detector, usually 10 db above input of just noise alone
(common definition of SNR).

> a programmer? I need to 'jury-rig' something
> to do the job. Any ideas?

Keeping in mind that the ability to read any PAL is directly
related to whether the security fuse is intact...

'Jury-rigging' a reader for something as potentially complex as a
PLD is not a simple exercise.

SHAMELESS SELF-PLUG: I offer reading, archiving, and programming
services for many kinds of logic and memory devices. I've checked those
devices against the Unisite's list, and it does support both the PLS153
and 157.

If this is strictly for an amateur radio project, I would be happy
to do the read/archive operation at no charge other than return postage.

If this is for a commercial project, it would be $24.50, and that
would include return postage.

See http://www.bluefeathertech.com/device.html for more details.

Hello all ,

I would like to install a VHF-UHF antenna on my motorcycle . It's a Suzuki GSX750 . I did some tests with a Diamond NR-770H and it works well . The only problem is that the antenna is to big for such a bike .
Afterwards i did a test with a Diamond NR-77 . The antenna is about 43 cm and that's about the size i would like to use .
The problem i have with this antenna is the swr , it's to high .

Anyone an idea how i can solve this problem ?

Many thanks .

Tom

Andy suggests:
Well, if it were me, I think it would look really cool on top
of my helmet.
As an alternative, you could mount a couple of Viking horns
on either side of the helmet, and use them as a dipole....
Use Texas longhorns if you want to go to HF......
Lots of fashion possibilities..

Good luck, Andy W4OAH

You might also ask yourself whether it really matters or not. If your signal is strong enough to begin driving the AGC to limit the system gain do you really care what the noise level actually is? Once the AGC threshhold is reached, if the signal strength goes up faster than the noise contribution from the system goes up do you really care what the noise level actually is?

Paul,

The reason is very straightforward. This is a boatanchor newsgroup
and it's mostly geezers who deal in old radios.

Geezers live in the past; WE don't think critically; the same tired
thoughts cycle through our heads. Even worse, many of us
hallucinate and make up reasons. You'll see several in this
thread.

Many geezers (to be fair, not all) are Xeno-phobic.

To them, Hawai'i is FAR away and never having been there, geezers imagine that it's a foreign country with different laws a strange language. In their minds, it's a not that far from Hawai'i to, say, Nigeria or Pakistan. Even if they could call the Honolulu police to report a deal gone bad, they would not be able to speak to them with finding a translater.

On the other hand, a geezer thinks, OK, I'm in Virginia, if a $30 deal in Kansas goes bad, I'll just get in the Biscayne and drive over there tomorrow, demand my money. I have that recourse.

People! As Paul says, Hawaii and Alaska are U.S. States.
They have senators in Washington. They vote for the president. As far as the U.S.P.S, FedEx, and UPS are concerned, those states are, like, right over there.

To Sprint and other fone companies, after 7 or 8 PM, just pick up your fone and those places are a free call. If you pay for wired service, it's 5 or 7 cents a minute.

Here are some actual numbers from www.fedex.com

2 day service - 20 pounds

Virginia to Kansas - $61.85
Virginia to California -$65.83
Virginia to Hawai'i - $66.87

2 day service - 60 pounds

Virginia to Kansas - $151.93
Virginia to California -$166.63
Virginia to Hawai'i - $169.24

About the same price for 2nd day service.

FedEx Ground service - 20 pounds

Virginia to Kansas - $12.70 - 4 days
Virginia to California -$16.03 - 4 days
Virginia to Hawai'i - $48.22 - 7 days

FedEx Ground service - 60 pounds

Virginia to Kansas - $28.40 - 4 days
Virginia to California -$39.08 - 4 days
Virginia to Hawai'i - $114.63 - 7 days

Three days longer and more dollars going ground to Hawai'i. But then Buyer Pays Shipping!

The same tracking and return receipt, the same laws govern the business deal. It takes about the same amount of time.

The reason that they say "lower 48" is that they think it's still 1936. It just comes out. There's no reason other than old

thoughts cycling in old heads like regeneration in a triode.

It's like hollarin' out,

Kids these days!

You call that music!

Dag-nabbit!

I've bought items from Canada and sold to Canada. One thing I don't like about it is that it's expensive to ship across the border. In fact, it's cheaper to ship though Canada to Alaska.

But then, buyer pays.

I just had the experience of buying from China, a DEGEN DE1103. If you don't have one, go over to the Bay and look up the seller LIYPN. $44 for the radio and $24 shipping and insurance. Took about 8 days to get here.

This is the best pocket shortware radio. Check out the reviews on the web. 1 kHz readout, better than 1 uV sensitivity, stable, 4 and 6 kHz filters. Covers 100 kHz to 30 mHz continuous so you can listen to AM broadcast, 160 meters, everything!

I can sit in my car, pull out the whip antenna and copy 7040 CW in the evening. I heard W1AW CW the other day, this is in Virginia.

SSB sounds good. Well, mostly good. I still can't understand the hollarin' on 27,000.

While you're buying and enjoying the DEGEN, think about global commerce and the fact that you just traded with a real foreign country.

Regardless of an amplifier's gain, the signal to noise ratio at its
output remains the same as the signal to noise ratio at its input.

Obviously - if its a linear amplifier!

In that case though, you should be worried about that nearby strong signal
dropping the gain of the receiver so you can't hear the weak signal,
the fact that the noise level may increase won't matter because the
lower gain will make the signal unreceivable anyway.

You may not be getting a proper counter-poise to the antenna system.

I would check grounding on the antenna and make certain the antenna
mount is in good solid contact with the metal frame of the bike.

You mentioned the larger antenna worked well. Does that mean the SWR
was good or it just performed adequately?

Which band is having the SWR problems?

What type of mount does the Diamond use? I am very partial to the NMO
type antenna mount. I know there are some antennas that use an SO239
type mount which is just a "UHF" connector on the end of a piece of
coax. These are not that well suited for 70cm operation although you do
see them quite a bit.

Also, how much power are you going to be putting into the antenna? I
would be concerned about RF exposure if its very much.

may be you are not thinking of cw... :)

Provided the SNR is good enough, you can filter and post-amplify your
weak signal, e.g. with a good AF filter, or a dsp.

Of course, if the IF stages are (reasonably) linear in response, you can
disable the AGC, but this would be no answer to the original question ;)

Just a word of caution:

Years ago, when the Brussels police had VHF radios mounted on BMW bikes for the first time, the ABS brakes stopped functioning when the transmitter was on (Not only the ABS, the brakes).

I suppose ABS brakes are more EMC proof nowadays, but you can not be too sure.

4040. Can I use a 120V Variac to get 220V?

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-08-18 19:31:03 UTC
From: w8kzw@hotmail.com

I want to reform the electrolytics in an amp I'm bringing back to life.
It runs high power, 220 volts ac only.

Can I use my 110 volt variac in conjunction with a 110V to 220V step-up
transformer to power up the amp? Obviously I'd not go key-down, but I
do want to ultimately get to the full B+ on the tubes.

How would I wire-up the variac / transformer, assuming it's possible?

Thanks in advance for the help, guys.

73,

==========

If an amplifier incorporates a noise generator or also behaves as a
filter, then it is no longer just an amplifier. My statement is quite
correct.

Reg.

of course, there is no real amplifying device which does not generate
noise; or, more precisely, there is no non-noisy real device at all :)

If you choose not to call "amplifier" a device which amplifies signals
if it has a non-unity noise figure, please feel free to do so - we live
in a (at least partially) free world... but you will be alone! >:))

Hi Tom,

You might want to try an HT antenna, such as the RH77CA - about 38 CM
long.

Hi Jeff, Wire the output of the variac to the primary of the transformer, and the secondary to the 220V power input of the Amp. You may want to remove the tube(s) or disable the filaments to reduce the burden on the step up transformer.
If the power transformer in the amp has a 110v tap, connect it up and then just use the variac. Be careful when you are doing this, there are all sorts of lethal voltages present. Good luck.

Thanks, Gary, but the devil is in the details.

The 220 out from the step-up transformer is from one end of the
secondary coil to the other.

The amp is essentially asking for two 110 V lines, working against a
common "ground".

So, somehow I must go from this:

0 <-----220-----> 0

to this:

0 0

0

and therein lies my confusion.

Here are the connectors labeled:

0 0
A B

to this:

0 0
C D
0
E

... all I need to do is to connect the dots!

Its relatively simple and easy. Connect a 100w light globe in series with the ac power input - this will limit current to a safe level. Run for 10 hrs or so, will give caps a chance to reform....start with the tubes in so the filament current draw limits cap voltage, then later remove tubes to get virtually full voltage across caps....

Don't be too hasty. Reg has verified he's got some coax that's much lower loss than anyone else can buy (it actually meets the predictions of his coax loss program), and has verified it by measuring it many times. Maybe he also has a secret source of noise-free amplifiers. You never know.

Unless something goes wrong. The abuse of international
transactions is legendary. Even eBay, PayPal, et.al. seem
to acknowledge it. As another poster observed, if you are
a large-volume commercial vendor, you can "eat" the
occasional transaction gone wrong. But if you are selling
one-off things (boat-anchors or not) on eBay, etc. it has a
significant chilling effect, no matter what generation you
represent.

Jeff, I would just leave the ground floating and connect C and D to the 220V secondary of the transformer. All you are trying to do is energize the HV supply of the amp. If you have a schematic of the amp, you should be able to figure where to supply the 220 to do just that.

Use a 1/2 wave antenna. Many marine shops stock VHF 1/2 wave antennas
for mast top mounting on sail boats. The beauty is no counterpoise is
required. I think some looking at Randall / Larson you will also find
they make 1/2 wave antennas.

For the typical automotive installed mobile whip you will need a
counterpoise. Generally on the auto that's not a problem as the body
is metal and presents a nice large ground plane.

: Not necessarily true. Noise, true natural noise, in a bipolar
: ...
: of how many factors go into noise generation within the
: transistor. :-)

So, if you have to engineer a (let's start with HF) receiver, do you think
it may better to:

1)
find a way to insert automatically a stepped attenuation (maybe
using a diode switched resistor network) and leaving amplifiers without AGC,
thus optimizing them for a particular gain

2)
build circuits with so high dynamic range that's completely impossible to
have input signals overload them (what's the dynamic range one should
normally expect at the antenna input, excluding obvious limit-case situations
where the transmitting output is fed into the receiver input...?)

3)
use the usual AGC

...I'm thinking the 1 could be a good solution if the demodulator had to be
a digital one. That way, a calibrated attenuator simply add bits to the ADC.
Hovewer, the 2 is very attractive, providing that all is analog, or the
ADC dynamic range is better than the one that could come from the antenna...

I've read most use the 3, digitizing the AGC signal maybe with a second
ADC channel, to have anyway a sort of more bits of resolution.
So probably I'm wrong and the right solution is the 3... but only if adding
an AGC never ruin amplifiers performance.

: There isn't much FM on HF. What there is would be in
: narrow-band Data mode signals. Some of that Data is a
: combination of AM and PM similar to a wireline modem's
: modulation.

In fact I was receiving 144MHz using a converter.

: What is needed in an investigation of this is a reasonably-
: well-calibrated signal generator with a calibrated attenuator.

Unfortunately I have only a Instek function generator, and I'm not
very satisfied with any intrument I bought from this firm...

Anyway, sooner or later I'll build a dds one...

Ah, another question. I have a very precise digital voltmeter. Very
precise, 6.5digits (this time from Agilent)... Unfortunately, it's
absolutely unable to handle RF.
I would like to build a "RF" frontend for it... Any ideas?
I'm thinking to a precise rectifier built with an OP AMP followed by a
OP AMP integrator...

> . . .

One night I heard audio in the background when listening to my direct conversion 40 meter receiver. It was designed specifically to be as immune as possible to AM demodulation, and since I had finished its optimization several years before, I hadn't heard any audio from demodulated AM. (It was common when I was using mixers with poorer balance and dynamic range.) It didn't take long to find the station with my home receiver. It was at about 7335 kHz, a religious HF broadcast station in San Francisco (about 600 miles from here). The broadcast was in Russian, so they were evidently beaming to Russia and I wouldn't be far off the main beam.

Some careful measurements showed a signal strength of 250 mV RMS at my receiver terminals. (That's 74 dB over the typical S9 value of 50 uV.) I was using a vertical 4-square array, which isn't at all optimum for that path. I hooked the antenna directly to my oscilloscope and could see the carrier and modulation.

I took the receiver on a visit to England, and heard the audio from a large number of AM stations in the background, so I believe the signal levels there from HF broadcasters commonly exceeded the 250 mV I saw only once at home.

The problem can of course be reduced by use of very narrow filters, but they're often so close to the 40 meter band edges that even that wouldn't be enough in most cases.

I've also encountered some staggeringly strong signals when operating Field Day, when a group with a high or even moderate power transmitter is on the next ridge or otherwise very close.

The bottom line is that I'd be hesitant to trust just about any number for a "worst case" maximum signal strength. Be sure to test any proposed design on 40 meters for a while from your location in Europe.

In theory the system bandwidth should not allow that strong signal to
hit the AGC. Of course practical systems this may not be true.

However, manual gain control helps if the stronger signal is not
overloading the front end causing gain compression and
intermodulation.

Since the SNR is established by the frontend the IF system can have a
more relaxed SNR.

However be wary of ICs like the MC1350 as the gain reduction occurs
the internal noise is bad. I've built several recievers using this
part and at ~10db gain reduction the noise jumps way up. I've gone
to cascode JFETs as the noise is more predictable and generally
lower. The device used does make a difference.

There's no "engineering" involved, just a crunching of numbers
AFTER you find the input levels versus AGC and how much noise
is actually generated...and approximately WHERE this excess
noise is coming from.

>1)
>find a way to insert automatically a stepped attenuation (maybe
>using a diode switched resistor network) and leaving amplifiers without AGC,
>thus optimizing them for a particular gain

I see no need of that at this point. "Getting fancy" with
extra circuitry is rather useless without knowing what the
problem all this fancy circuitry is supposed to cure.

>2)
>build circuits with so high dynamic range that's completely impossible to
>have input signals overload them (what's the dynamic range one should
>normally expect at the antenna input, excluding obvious limit-case situations
>where the transmitting output is fed into the receiver input...?)

That's NOT the issue here.

Noise and signal-to-noise ratios are only important at LOWEST
signal levels, not the highest.

>3)
>use the usual AGC

Why not? Decades of designs in many countries have successfully
operated with "usual AGC." [voltage-controlled, sometimes
current-controlled gain stages driven by a DC control line]

>...I'm thinking the 1 could be a good solution if the demodulator had to be
>a digital one. That way, a calibrated attenuator simply add bits to the ADC.

Experiment any way you want but I can't see that as your cure.

>I've read most use the 3, digitizing the AGC signal maybe with a second
>ADC channel, to have anyway a sort of more bits of resolution.
>So probably I'm wrong and the right solution is the 3... but only if adding
>an AGC never ruin amplifiers performance.

A rather common (for decades of designs and production) AGC action
is no more than 6 db change in output for 60 to 100 db of input
signal (carrier) change.

AGC should be approached from the standpoint of a servo loop.
The "error signal" is the change in carrier level at the
detector. The controlled items are the RF and IF amplifiers.
The time-constant of the error feedback loop (what is commonly
called "the AGC line") is quite slow but fast enough to try to
keep detector level constant through flutter (rapid reflections
at VHF and up) and ionospheric path variations.

If "the AGC line" somehow has some noise in it, that noise is
probably going to change RF-IF amplifier gain. However, the
frequency of that noise is going to be low; it is band-
limited by the usual AGC line decoupling.

Let's look at SNR with low to higher antenna input levels:
1. Assume you have (for example) 1 uV of noise at no-signal.
2. If the RF signal is 3.16 uV then the signal-plus-noise
to noise ratio is 10 db.
3. If the RF signal is 10 uV then the signal-plus-noise to
noise ratio is 20 db.
4. If the RF signal is 31.6 uV then the signal-plus-noise
to noise ratio is 30 db.

The common (for about 40+ years, internationally) level of
receiver sensitivity for AM mode signals is a 10 db signal-
plus-noise to noise ratio. That's an easy test, done by
connecting an AC voltmeter (that can measure RMS voltage)
to the detector output. With no signal input, all you get
is front-end noise; note that. Apply a known-level RF
source to the antenna input, adjust that level to be 10 db
higher than the noise level measured with no signal input.
Note the RF source level; that is the "minimum
sensitivity" level for the common "10 db S+N:N" criterion.

For FM or PM it is a bit more complicated. FM and PM
rely on quieting through the Limiter stages ahead of the
FM detector. For most tests of FM/PM sensitivity you NEED
a known-signal-source-level to determine the quieting.

>: There isn't much FM on HF. What there is would be in
>: narrow-band Data mode signals. Some of that Data is a
>: combination of AM and PM similar to a wireline modem's

>
>In fact I was receiving 144MHz using a converter.

That data was omitted. Have you checked out the converter
insofar as adding noise? You can get a rough comparison
by using another HF receiver.

Have you checked your internal (to HF receiver) FM
demodulator characteristics? Do you have the manufacturer's
specifications on that? Since nearly all FM/PM demods
use Limiters, they normally operate with AGC off.

>: What is needed in an investigation of this is a reasonably-
>: well-calibrated signal generator with a calibrated attenuator.

>Anyway, sooner or later I'll build a dds one...

You can't work in the dark (without instruments) when
trying to troubleshoot electronics.

A DDS (Direct Digital Synthesis) signal generator gives
you very precise FREQUENCY. For years there have been
L-C oscillator based signal generators which have been
stable enough in frequency to determine AGC action.

What you really need to investigate the AGC is PRECISE
RF ATTENUATION -and- a way to calibrate the maximum RF
output. [an ordinary diode detector could do that if it
was itself calibrated against a known RF source LEVEL]

>Ah, another question. I have a very precise digital voltmeter. Very
>precise, 6.5digits (this time from Agilent)... Unfortunately, it's
>absolutely unable to handle RF.
>I would like to build a "RF" frontend for it... Any ideas?
>I'm thinking to a precise rectifier built with an OP AMP followed by a
>OP AMP integrator...

The usual method of making a "precise" RF voltmeter is to
begin with a wideband video amplifier with gain controls
setting the gain in the full-scale ranges desired.

However, the BACK END needs attention, particularly if you
want TRUE RMS measurement. The "less precise" HP3400A
AC voltmeter could do that True RMS within 1% using an
analog meter readout (mirrored scale on meter). The
3400A used a pair of matched heaters and thermocouples.
Amplified AC heated one heater. A high-gain DC op-amp

had inputs (opposing) from both thermocouples. Op-amp output heated the second heater. This was self-balancing. The AC Voltage indicated actually came from the DC op-amp output.

If you are going to measure AC-RF volts of both sinewaves and noise, you need True RMS indication. Without that the noise (random stuff) read by simple averaging rectifiers will be DOWN by as much as 50% compared to a sinewave input. There are three basic types of AC voltmeters made: Rectify-average (common to handheld multimeters); Logarithmic (now a standard of high-end bench multimeters) using special ICs for True RMS conversion to DC; Thermal (now out of favor in new designs but using the first-principles of measuring the effective heating of a resistive load). Thermocouple sensors are reliable, can handle overloads, but a diode string biased for forward conduction can produce DC voltage changes of -2 mV / degree C heating.

For some references, you can search the Internet for "RMS to DC" conversion, or begin at www.ednmag.com, go to their Archives button, select issue for May 11, 2000, and look at the "How It Works" article by Jim Williams of Linear Technology Corporation. LTC made an IC that was a dual heater-sensor, the LT1088, but that IC is now discontinued. The article shows a "front end" as well as the whole AC voltmeter circuit.

I have to disagree on the MC1350 and way back 30 years to its
predecessor, MC1590. The prototype HF receiver presently on
my workbench has a NF of 5.5 and that hardly rises more than
that with AGC current applied to the AGC pin.

BTW, that receiver, single-conversion with one IF at 21.4 MHz,
uses only MC1350s up to the detector, including the one mixer
stage. [LO is a separate PLL board]

> you're blowing up the caps.

Rubbish. Where do you get this 25w figure from, and across how many
capacitors in a (typical) series string - oh, and lets ignore idling
current through transformer and bleeeder resistors, and filamnet
current drain, and blowers, and dial lamps, and.....which would further
reduce available volts across the caps.... And whats this "imagine a
scenario" stuff - I thought you were trying to be precise and were
chiding me for my lack of hard data....

So, what voltage do you set the variac too? - how do you work it out?
>
> It's always helpful to disclose the parameters of the situation
> when asking for advice. Otherwise, you'll get 10 different
> solutions based on 10 different assumptions, none of which will be
> correct.

True. There are probably 10 different ways of puting out a fire, but
the easiest is dumping a bucket of water on it.

Honestly, this is ridiculous - most modern (ie, last 40 years) caps are
fine, will survive horrendous abuse, and unless you have the
manufacturers data sheets for these capacitors, (and the power
transformer, and the rectifiers) how are you going to set these
parameters anyway? - this is a linear amplifier, not the space shuttle.

Why do people insist on making things sooooo complicated, almost
theoretical physics level - it isnt. Dont let irelevant theory get in
the way of practical electronics.

The intial switch on of ANYTHING that hasnt been powered up for years
is going to be the time it dies - at least the bulb will stop it
bursting into flames, the variac method will jsut slowly ramp up volts
until something blows catasphropically (I know, used to do this, got
sick of replacing fuses in the variac.)

As well, you have the added complication of multiple, lashed together
transformers which MUST all be correctly phased and able to take the
load current . a recipe for confusion at least.

And no, I cant spell. Spend too much time with soldering irons rather
than physics journals.

Andrew VK3BFA.

I ship to anyone that wants to pay for it. I do avoid APO/FPO shipping, and not because of scams but because of very very poor delivery chances on anything not a 1 ounce letter.

I sent several boxes of supplies to friends serving in Iraq with the US Marine Corps...most of the boxes languished in a warehouse in Germany for about 4 weeks before being hauled to Iraq...then it was another 2 or 3 weeks befire they actually got the stuff. Needless to say, never ship a puppy or kitten to a war zone. I have one realative that was in Iraq for a year (the last time). I mailed him a Christmas package at the end of October. He got home in February and still hadn't received it.

I ship DX but the buyer has to pay for the shipping.

Yes, shipping to OIF/OEF is very very slow. This is because nobody wants to
go in there. Regular fuel shipments can take 2 weeks to cross the country.
Shipping to APO/AE (Europe), APO/AA (Americas) and APO/AP (Pacific region)
is fairly steady, at least going by Priority. Parcel Post or Media Mail go
by SAM (Space Available Mail) and can take months to get ANYWHERE within the
military postal system. This is because EVERY other class of mail gets
priority over SAM, and some of those parcels don't leave the mil hub for
weeks (stateside).

What I've done sending goodies to our troops is to use the flat rate
Priority Boxes available free at the post office. All you can stuff
into it for the 2 pounds rate or $8.10. Mose have been delivered within
a couple weeks.

If interested might check out http://www.anysolder.com

Read EMRFD page 6.16 (ARRL press) they tested the 1350 and at the
point where the gain cell has equal conduction on both legs the noise
rises significantly. I duplicated the test fixture and yes, it's
noisy, from around 6db to around 11db in my fixture when gain is
reduced by 10db and that was at 16mhz. In a reciever that used
it I went to two cascode stages using JFETs and the difference noise
was notable for weak signals just into the agc range. I restrict the
1590/1350/ca3028 for lower perfomance recievers now.

I also verified that the 1590 does same and also the CA3028
wired as differential AGC. Even tried three 2n3904s and
same result. The agc range was good and at full gain the
noise was ok but the noise increase at partial agc was surprizing.

> BTW, that receiver, single-conversion with one IF at 21.4 MHz,
> uses only MC1350s up to the detector, including the one mixer

I do most of my RX experimentation at 6/ 2M and 70cm SSB so
noise and overload perfomance are important to me. Images
are also a big problem as I'm near a lot of VHF/hf broadcast.

Allison

Apparently I hit some nerve on my disagreement.

My first experience with the MC1590 was in 1973 and a need to
operate over 55-64 MHz. Electronic gain control was essential
and it had to be fast. Motorola supplied some additional
information which was later incorporated into appnotes.

The MC1350 was marketed around '73 along with the MC1330
video detector as a TV IF system. It didn't sell that
well in quantities (presumably) and both were dropped
from active production (Lansdale acquired masks and now
makes the MC1350). The 1350 (8-pin DIP) should use the
same die in the metal can MC1590. While neither one was
ever touted as a super-champ low-noise device, it is what

I consider respectable as to NF. The fact that it has
differential input and differential output is convenient
from the standpoint of circuit design. Especially so when
input impedances (each side) has a dependable 5K R in
parallel with about 5 pF total capacitance. Gain of both
begins to fall above 75 MHz with output loads of 100 Ohms
resistive. I've found no noticeable difference between
differential input v. single-ended.

That IC is what I term a "double Gilbert cell" in that
AGC control current affects both differential inputs
equally (or very nearly so). Whether one connects to
both inputs or just one shouldn't make any difference
other than output gain.

>I also verified that the 1590 does same and also the CA3028
>wired as differential AGC. Even tried three 2n3904s and
>same result. The agc range was good and at full gain the
>noise was ok but the noise increase at partial agc was surprizing.

I've never encountered any "surprising" increase in noise
at any AGC input to a 1590 or 1350 causing partial gain
reduction. That is as true in 2005 as it was in 1973. If
there is a SNR of 10 db at an RF carrier input of 3 uV and
a gain reduction of 10 db for a 10 uV RF input results in
3 db more noise in the front end, the SNR with a 10 uV
input is still higher than the one at 3 uV. What has been
"lost" there?

Let's look at the original problem starting this thread:
There was a claim of "increased noise" with AGC on, but
no quantifiable data. The sudden segue to stating that a
certain IC is "bad" is a leap that defies good design
practices to me. I'm not impressed that the ARRL had some
test data in a publication; having been hands-on with this
Motorola design for a number of years, I have a number of
RCA lab notebook pages filled with my testing of it along
with a patent involving it granted 1974...besides my own
hobby notebooks.

Low-noise input amplifier design is an entirely separate
subject and there are a number of other active devices
which can do lower NFs than 5. What was orignally needed
was some way of getting some numbers and test configuration
of Andrea's problem...to pin down a possible reason for
alleged increased noise with AGC applied, presumably a
"partial AGC" application. [I can't quantify "partial"
as a numeric value...maybe others can?]

>I do most of my RX experimentation at 6/ 2M and 70cm SSB so
>noise and overload perfomance are important to me. Images
>are also a big problem as I'm near a lot of VHF/hf broadcast.

[<shrug> I live about 6 miles from 50 KW KMPC on AM...]

If we can get back to the original claim of "increased noise with AGC applied" we might be able to help Andrea some. We don't know what Andrea has for a main receiver and interjecting some "badness" remarks by the ARRL about a certain IC isn't going to help clarify Andrea's problem.

I frequently see postings in the ham radio related newsgroups for items currently being offered on E-Bay.

All to often I that items will be shipped only to the lower 48 states, leaving hams in Hawaii, Alaska, and Canada out of the picture. What is the problem. In Canada we are well served by FEDEX and the United States Postal Service. Amateur radio equipment crosses the border with out any problem. I realize that Hawaii and Alaska may be a bit far from the "lower 48" but the same delivery services are available even though surface transportation may be a little bit slow. In the US you also have UPS, the folks in Brown which we Canadians prefer not to use because the often make the border crossing more difficult than it needs to be and we don't like getting stuck with brokerage fees.

So why the discrimination, if the buyer knows that delivery may take a little longer and is prepared to accept the fact then it becomes a non problem. If the seller is intimidated by the prospect of complicated paperwork, he needn't be. Please leave it up to the buyer to decide whether he wants to bib or not.

I can not speak for shipments to Europe, Africa, India, China, or the South Pacific but for fellow Americans, or friendly northern neighbours, I think that people should be prepared to deal with us.

Thanx for letting get this off my chest and I realize that I have cross posted this to four different newsgroups but I wanted to get to a broad audience.

Wide open and at >20db reduction the noise figure is not bad at
all. Only that the apparent increase is noteable. I've seen it
occur with other topologies including simple bipolar or FET
stages (even tubes).

Those are the feature of the part that makes them desireable.

> That IC is what I term a "double Gilbert cell" in that
> AGC control current affects both differential inputs

I call that circuit an analog four quadrant multiplier for what it
does not how it's made.

The feature of the Gilbert cell that applies for the AGC use is the
lack of DC shift at the output points keeping downstream
DC coupled stages at their undistrubed bias points.

However the active device that is in the agc control
positions is still a noise generator (as are all active devices)
and as agc increases it's contribution is additive to the
RF path devices. Makes little difference if the node where
outputs are combined see no DC shift the various diff amp
transistor as individual pairs do see a significant shift (100%
collector current to near 0).

It's easier to see using the older MC1550 or CA3028 diffamps
or even discretes in a diffamp with current source.

>>I also verified that the 1590 does same and also the CA3028

> "lost" there?

The surprize is that I'd not considered the possibility that
the SN+N/N could degrade unevenly due to applied agc.
So I'd never paid attention until I was trying to improve an
earlier reciever design (ca1978) of my own and at the same
time aquired a copy of EMRFD and did some testing to verify
their resuts. Since the design was optimized for low RF
gain and high overload thresholds I was revisiting anything
that could better the design without loosing those features.
Note it's a single conversion system with high IF. The
problem was a MDS of -136dbm but the 10db Signal+N/N
point was around -110dbm and at ~121dbm it was worse
than at -130! The front end was common gate RF amp
(2n4416s) driving a pair of 4416s in a single balanced
mixer. Low noise but limited gain for better overload
performance. No agc before the IF. If needed there

are switchable resistive attenuators (3, 6,12db or 19db total).
Measured gain from antenna to IF is only 16db (after all losses).
Disable the agc or increase the threshold and it wasn't as
measurable or appeared to disappear.. The hunt was on.
The results were a surprize as there is no data for noise output
with no input or signal to noise with gain reduction. My Moto
databooks go way back, as do my National, RCA and
Signetics library. More current datasheets do not reflect any
improved information.

The revised RX used two stages of mpf102 Jfet in cascode
plus a diferential pair of 2n3904s to resolve the 5-10V agc to be
compatable with the new fet amp to replace the two MC1350s
and the problem of decreasing signal to noise as signal increased
with agc active disappeared. Not to say the fet amps did not do the
same thing only that the rate of noise increase was a smoother curve
from max gain to min gain. In retrospect a delaying AGC to the first
of the two 1350s could potentially have the same effect but was not
investigated. I may revisit it at some time as I still have the
original if module in the junkbox.

> Let's look at the original problem starting this thread:
> There was a claim of "increased noise" with AGC on, but
> no quantifiable data.

Thats a problem, the lack of data or information on the circuit.
Also I've repaired a few commercial radios that due to component
failure or "golden screwdriver" had the various operating conditions
sufficiently altered as to cause a similar problem.

> The sudden segue to stating that a
> certain IC is "bad" is a leap that defies good design

> RCA lab notebook pages filled with my testing of it along
> with a patent involving it granted 1974...besides my own
> hobby notebooks.

That's nice but are the test results in error from two different
sources? No.

However, it's was a noteable weak point. But calling it bad is
your words. It's a point that needs to be understood and
allowed for. In a design with more RF gain and/or less mixer
noise it many not have been a factor or less of one. Also in the
case that brought it to a point for me even altering how agc is
applied might have achieved a better result.

Since the 1350 is at IF for most designs the noise is likely from
front end causes should be investigated first. One would hope the
design had secured the system noise performance before

the IF. However in low gain systems or system with no gain
before the mixer and first filters this may be problematic.

10 miles from the Needham towers in MA. Not less than 8 VHF
broadcasters, then the usual crowd of UHF and now the
HDTV-UHF broadcasters and no small party of FM
broaccasters.

Oh and WKOX 1200 AM three miles away.

Then I have 9 hams within a 1 mile circle and two within 1500ft
running KW level at VHF. RFI are us. I understand overload
as >+15dbm on coax is common here.

It's an interesting design challenge to do low noise figure RX
and at the same time be overload resistant in a harsh environment.

> If we can get back to the original claim of "increased

Having tested and understood the problem I would say the
authors of EMRFD did a fair job of pointing out the points where a
device needs better understanding. A blanket "it's great" is lore,
testing it and understanding it is engineering. Having done the
work to understand it better I can appreciate the perfomance of
the part and it's limitations.

I still use it and have a tube of them because it's a useful part.
Just like the often reviled SA602 mixer.

It's relevence is I've seen this before and understood it's origin
and also elsehere. The other aspect is that if a commonly
accepted part is not fully understood and can lead to undesired
effects then, why not others. AGC is not a trivial thing to be
tacked on and considered a problem solver. Protects the ears

but it's place in the reciever is not always understood. It does not always solve things like gross overload at the front end or possibly further down or outside the agc detectors bandwidth.

But a lack of information about his radio doesn't help us either. We do not know for instance what topology is used for RF and if any agc is even applied to it.

I had this happen with a 3 week old amp. One of the low voltage caps
blew. It sounded like a shotgun being fired in my basement. The
"can" hit the top of the 8877 amp and flattened out like a 38
wadcutter hitting something solid.

It doesn't have to be a boat anchor to have a cap blow.

Thanks for the (mostly helpful) replies, guys.

Applying each one of the two ends of the 220V coil of the transformer to the 220V legs of the amplifier plug made sense. I guess I was mostly wrestling with how to handle the gounded / grounding lug of the amplifier plug.

Gary said to just leave it floating, but wouldn't grounding it be safer?

Since you will be running the variac through a 110/220v isolation transformer, you will lose reference to the utility ground, so there is no reason to connect up the ground on the amp. If by some chance the 110v windings in the amp are on different cores, or are actually 2 transformers, then you would need a common (ground) reference for the two. This is probably not your case, be nice if you had a schematic.

Sorry for the short answer. The receiver is a Yaesu FR-101 with his internal 2m converter. Actually, I'm doing some recalibration but I didn't found at now nothing really out. I just noted that, mostly noticeable in FM mode (by noise increasing) but present in all modes looking s-meter, the response of the IF was not a gaussian with a flat top. In the center there was a little decreasing area. If you tune it perfectly, you had a sligtly less signal than little up or down in freq.

So I started recalibrating. I had stopped because I had trouble with the noise blanker. In the manual, there is a indication of a test point where hook a voltmeter, but there is not any test point nor any indication on the schematic where the exact point is. The transformer is T116, maybe someone could help. Tomorrow I'll figure out what to do, I think I'll hook the voltmeter as to measure the voltage rectified, at the gate of the FET. If you have the schematic (it's freely downloadable in many places) maybe you could tell if I'm right.

Anyway, thankyou very much you want to help troubleshooting my receiver, but I was using what I noted (increase in noise with AGC on) mainly to start a general discussion about AGC implementation and effects, and his future in digital receivers as well as in homebrew very high-end ones. It has started, and it's very interesting.

True. But why lose the chance for an argument? - my issue was with the over complication of a simple task....and if someone needs to ask questions on how to set up a variac and a transformer, then the keep it simple approach (ie, the light bulb) has much to recomend it.

Andrew VK3BFA.

Dual conversion for HF and triple conversion of 2m. There would
not be RF agc on the 2m converter. In FM modes you should see
limiting so agc is behavour is different.

4084. selecting bias inductors for amps

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-08-23 11:08:57 UTC
From: hq105862@hotmail.com
Message-ID: <1156331337.369646.48320@i3g2000cwc.googlegroups.com>
Source record: 10885

Hi,

I've been sleceting inductors for chip amplifiers based on the datasheets, but I would really like to understand what I should be doing.

If I am designing an amplifer that is to operate over say 3.4 to 4.2GHz, should I be looking for an inductor with self resonance above that band, or at centre frequency, and why?

(I know that at self resonance, the inductor will be resistive, below inductive, and above capacitive, but I don't know what I should be looking for.)

Should I be looking for high Q or low Q, and for what reasons would I choose each.

What numerical values actually equate to High Q and Low Q?

Is Q of 9 low, and Q of 35 high, for example?

thanks

> If I am designing an amplifer that is to operate over say 3.4 to
> 4.2GHz, should I be looking for an inductor with self resonance above
> that band, or at centre frequency, and why?

The "safe" advice is to choose one where the SRF is above the band you're designing for, but strictly speaking you can usually get away with SRF within the band or even a little below.

Your inductor can be modeled as an "ideal" inductor with a capacitor in parallel. Up until resonance, the reactance of the physical inductor is positive and varies (roughly) linearly with frequency. At resonance, the reactance of the capacitor is equal but opposite that of the inductor so you have Yin = 1/sC + sL = 0 --> an open circuit. Above resonance, the physical inductor still has positive reactance but now it's decreasing with frequency... not what you want!

> (I know that at self resonance, the inductor will be resistive, below
> inductive, and above capacitive, but I don't know what I should be
> looking for.)

You're looking for an impedance that's "significantly" (conservately, at least 10x but realistically often 4x is fine -- the more conservative you are, the less insertion loss you'll get) greater than the characteristic impedance of your transmission line. (If you run it through a calculator, you'll see that 50 ohms in parallel with, say, j*50*10 is still *very* close to 50 ohms, and even 50 ohms in parallel with j*4*50 really isn't half bad).

> Should I be looking for high Q or low Q, and for what reasons would I
> choose each.

About the only upside of a high Q inductor for biasing is slightly lower insertion loss, and a very significant downside is that the inductor's resonances above the band you're interested in will be "strong" and can cause large (>1dB), narrow perturbations (resonances) in the system's insertion loss. A lower Q will tend to "smooth out" those resonances.

Indeed, if you're looking to build a wideband bias circuit, you often use several inductors in series (small-medium-large, say) *with resistors in parallel that purpose de-Q the inductors*. Without the de-Qing resistors, the high-Q inductors have nasty interactions (two or three together will conspire to appear as something approaching a short circuit at some frequency!)...

> What numerical values actually equate to High Q and Low Q?

I'd call "high" Q>100 and "low" Q<10. High Q inductors are generally not obtainable in "chip" form; you need air cores or exotic dielectrics to get such high Q's at VHF/UHF. (For that matter, at least in my mind, high Q inductors generally shouldn't be used for biasing -- they're used for filters. :-))

> Is Q of 9 low, and Q of 35 high, for example?

35 is "middle of the road, drifting towards low." Q=35 is a decent inductor to use for biasing... not too lossy, but lossy enough to avoid the resonance problems discussed above.

Are you sure you are seeing an AGC problem? What you describe above, with slightly less signal in the center, is typical of a *filter* with dip in the middle of the passband. This is *not* a result of increased signal strength causing more AGC and thus more noise when the receiver is tuned to exact center on a signal. It is the result of a filter design choice (lower cost) or the result of the filter tuning (tuned for better shape at the edges which causes more dip in the middle).

Without knowing more about the receiver I can't make any guesses as to what is in play here but I question if this is an AGC artifact.

The reason for that is Hamfests and Swap Meets in general are DEAD.
Finished! Kaputski! Stick-a-fork-into-it! (etc..etc..)
Dayton Included too. I went to Dayton this year after a 5 Year sabbatical.
Fully 1/3'rd of the outside vendor spaces were empty.
Just 5 Years ago this was a rarity and 10 years ago it was downright
impossible.

Why? Reasons are many....aging ham/swl population, SK's, health/travel,
cost
of gas food lodging etc... then again, why drive when you can order new
online
an it's at your door via UPS in a few days?

Ham radio is changing and it is aging. more than HALF the hams I used
to talk with on 75M HF just from 10 Years ago are all SK's. That alone
speaks volumes folks!

E-Bay did not kill hamfests. Hams themselves are dying off and
most of the stuff is ending up on e-Bay where it's a feeding frenzy.
This too will end in a few (10?) Years time also.

In short....Wayne Green (W2NSD) had it right all along folks.

Enjoy the rest of the ride.

Yep! All them are reasons I have stopped attending Dayton and many other hamfests.
But ebay is also a contributor. I got some 2m old crystal rigs via ebay and shipping
cost more than the radios. My last time at Dayton a few years ago it was a costly
one day ticket (my health not good either) and $8 to park in a handicap parking spot
that might as well been down at the mall it was so far. I thought handicap parking
meant CLOSE to the doors. With Gas about $3 a gallon depending on the wind...
another $100 bucks down the tail pipe. The items for the most part these days
are "vintage" things that have been to more hamfests than I have or they are
"Like New" and priced as new. Most "Homebrew" projects in magazines and
books these days have little chance of success with the ol' junk box and requires
a large part of it to be bought and often via mail. "What radio supply store?"
When you do get to a hamfest the people are rude, bump into you, step on you,
just same as many drivers on the road have aggressive attitudes. All the fun of the fest's
has gone as well as a pleasurable drive getting there has gone. And the total cost
of just going is 1/2 the cost of a new 2m rig. UGH!!

Oh and don't forget other tech'y things like the cell phones that has displaced a lot
of would be radio operators for maybe contacts with more secure and reliable
contacts. 2m and 70cm not as impressive as it used to be. "What do you mean,
point the antenna UP?" LOL ;-) My wireless home phone and my computer
has more MHZ than my radio now. ;-(

Maybe it's as well though. Having started in the TUBE days and seeing SMD parts
now I can't find, or use if I could find them for projects... might be appropriate that we go
out together in a few years.

Sorry I missed the original post to this thread. Hope it didn't wander too far...

Have rag chew paper too . LOL

That has long been common knowledge to those of us who noticed the
downhill slide of radio receiver quality when the Volume knobs became
larger than the Tuning knobs.

<snippety>

You could have fooled me. There's nearly a dozen swaps every year,
at different times of said year, here in the PacNorthwest.

The SF Bay Area, Lawndale (southern California), and San Diego all
have monthly hamateur swap meets. I regularly attend several. They're
about as far from "dead" as one can expect.

Yes, Greed-bay has had an effect on the quantity and variety of
equipment that shows up at such events. However, there still seems to be
plenty to go around.

Suggestion: Research before you generalize.

> that might as well been down at the mall it was so far.

I believe the admission prices at Dayton are largely driven by the "going rate" for the Hara Arena; renting large spaces like that is *quite* expensive. The prices are certainly not high compared to similarly sized non-amateur conventions I've attended.

The handicapped parking largely seems to be an issue because *so many* people request it these days; it's impossible to have literally 300 handcapped parking spots *all* close to the door. I agree that you're probably better off parking in a handcapped spot at the mall and riding the shuttle bus.

I believe that for hamfests to continue being successful, they're going to have to concentrate more on educational seminars, demonstrations, and events (transmitter hunts, contests, etc.) rather than just a swapmeet.

I think it's a often sign of trouble when any organization seems to spend an inordinate amount of time worrying about their own numbers rather than just engaging in what it is that brought them together in the first place and letting the membership numbers drive themselves. Ham radio (or at least the ARRL) seem quite preoccupied with membership levels...

> My wireless home phone and my computer
> has more MHZ than my radio now. ;-(

:-) Yeah, I know what you mean. To some degree FCC regulations have held back the development of amateur radio, but on the other hand the number of amateurs out there who could successfully *design* or even *assemble* something similar in complexity to a cell phone is miniscule.

Parts availability today is, in many cases, far better than ever before. Mouser and DigiKey are real treasure troves of inexpensive RF parts, you know in the click of a mouse what the stock status is, and they deliver quickly.

You can get a similar appnote from QuadTech at www.quadtech.com
"LCR Measurement Primer," 4th Edition, 60 pp. QuadTech took over
the LCR bridge and electronic instruments from General Radio Co.

A few sites have copies of General Radio's "Experimenter" which
might be of interest to those looking behind front panels for
intimate details. [nothing beats the HP Journal in my mind but
others mileage may vary]

Also, at www.tm.agilent.com there is a copy of Hewlett-Packard
Journal, Volume 29, Number 4, December 1977, which gives a good
description of their old HP-4262A LCR Meter.

<tirade 2 deleted>

Well, you could do the math...it's easy.
I was too lazy to do the nonlinear math for the lamp.
But an experienced (good) engineer knows how to
quickly make approximations to weed out BAD ideas.
That skill is uncommon. You'd think it's obvious.
And the GOOD engineers do it instinctively.
But the other 99% just don't get it. They'll head
down the dead-end road 'till they reach the end
then bang their head on the barricade. A (good)
engineering manager shines a light on those dead-end
barricades. See, there are situations where a light
bulb can fix a problem.

When the problem is largely unspecified, a (good)
consultant requests specificity. It's easy to
ASSUME that it doesn't have tube rectifiers, but we
don't really know.
When the consequences can be BAD, and the problem
is unspecified, a (good)
consultant recommends a conservative approach.
And when the original poster merely requested clarification
on a conservative approach, it's low risk. Proposing
a higher risk option is ill advised.

A (good) teacher tries to understand the implications of
the question and keep the student out of harm's way.

I'm gonna pull some numbers outa my ass, 'cause that's
where I keep my common sense. That way, I get a new
supply every day.

The series light bulb likely works 99.99% of the time.
But doing nothing probably works 99.98% of the time.
If your estimates are different, state them. How many times
have you turned on your amp? How many times has it blowed up
because you didn't reform the caps?

At the risk of repeating myself...IF your caps NEED reforming,
it's wise to bring them up slowly with a variac. Adding the
series light bulb will make it even safer, but only if appropriately

sized and you're paying attention...there's that pesky specificity again.

If you're really interested in reforming caps, take them out
and use a variable power supply with a BIG resistor separately for each
one. Do it very slowly...but nobody really asked that...
Ya see, if you've got series caps...more pesky specificity...
a leaky one can cause the good one to fail. But nobody aked that
either. And maybe they've got equalizing bleeders that can mitigate
the problem...assuming one's not open and making the situation
worse...but nobody asked that either.

An interesting question might be, "how do you refurbish an amp that
hasn't been turned on in a while?" But nobody asked that...

Shooting from the hip, firing off the one true, onesizefitsall, solution
when you don't know the particulars and are not accountable for the
result is...
well...it's the "internet way"!

mike

RANT
ON.....
I am NOT disputing your theory - its correct as far as it goes, youve left out lots of other factors that, ideally, should be considered in this case, But its irrelevant to the original question. And in real life I would ignore it as being too anal retentive.

If the original poster needed to ask how to hook up two transformers, then your quasi mathematical analysis would be totally innapropriate to the job specifications. Did you think of this at all? It is covered in most 1st year engineering course...(RTFM)

My method, with the light bulb, might be crude, (it is crude, so?) but it will work. And have proved that it works, more times than I can remember. Linear and switching power supplies.

A simple question - using the light bulb method, whats the WORSE that can happen? If the amp is horribly faulty (and lets not even bother about doing insulation tests on the (old) transformer, that would make it even more complicated) then the light bulb will light to full brilliance.

Even an engineer could see that theres something wrong, and then fault find it. (After doing the math, of course)

The variac method - again, the same simple question - whats the WORSE thing that could go wrong. And I will answer that, not from theory, but from practice. The voltage is slowly ramped up until something fails abruptly and catastrophically. With no current limiting beyond a mains fuse in the variac (You did check its rating, didnt you?) the electros

will disintigrate like shotgun cartridges generating lots of additional work. (no harm was done to the person, being a trained engineer they had safety goggles on...didnt they?)

(The above assumes its a linear supply - if its SMPS, then the switching devices sacrifice themselves in a vain attempot to save the fuse)

I have spent my entire working life in this field - working as a technician fixing up the design problems of engineers. Stuff that any competent technician would know NOT to do, from practical experience. In my working life, I have met approx 5 competent engineers. The rest were theoretical bullshit artists who soon moved into management purely on the strength of having a degree - they were as hopeless at that as they were at engineering, but there they had less chance to do actual damage.

Are you a "working" engineer - do you own a soldering iron? - lots of theory, plenty of if/but/maybe/ because/planning, but no real appreciation of what the problem is - firing up an old amplifier. Thats all - its not a design exercise, theres no cahce of a Nobel Prize in this one, the project doesnt need to be managed, no consultants needed to give a "proffessional " opinon, no SPICE models needed - just how to power up an amplifier with minimal damage.

RANT
OFF.....
.....

woo.....

TIRADE
ON.....
.....

And I am heartily sick of "armchair experts" making life bloody complicated when someone asks a legitimate question that is best answered without a theoretical textbook analysis - I have seen far too many people at radio clubs made to feel inadequate because some smartarse engineer has given a long winded incomprehensible, irrelevant answer to a simple question. These people leave, and dont bother to come to any more meetings, or ask any more questions.

One of the best teachers I ever had was an engineer - a very rare person, a brilliant teacher and a competent engineer. He woked out where the question was coming from, ie the level the student was capable of understanding - he then started from basic principles, with great patience, and took the student forward until they could understand the rocket science behind the question.

And if you want to see a good textbook using this method, grab a copy of 'The Art of Engineering" by Horowitz(sp) and Hill. read it - you might learn something from it about communication skill.

If you cant help, dont hinder.

Andrew VK3BFA.

: slightly less signal in the center, is typical of a *filter* with dip in

I have the filter dip; it was not cured with realigning, but realigning was
anyway helpful to gain a dB or two.
I also see that disabling AGC cause less noise in FM while listening to 2m
converted to HF by the internal converter of the Yaesu FR-101. I didn't check
if enabling or disabling AGC cause any change in the filter dip, anyway I'll
check and report soon.

: Without knowing more about the receiver I can't make any guesses as to what
: is in play here but I question if this is an AGC artifact.

It uses a MC1496G as mixer and two CA3053 as IF. Plus some DG FETs, in first
RF amplifier, after the mixer... What information do you need?

A block diagram would be helpful. Do you know if the AGC is being derived from the audio chain or from a sampling circuit in the IF chain?

Where are you turning off the AGC? In the FR-101? It sounds like you have a frequency converter feeding an HF receiver with an FM position. Is that correct? Could you just as easily tune in 2-m SSB as well as 2-m FM?

I can't seem to grasp why turning off the AGC would result in *less* noise, especially on FM.

The "noise factor" of the system is probably fixed by the converter, not the receiver. It would be like hooking an antenna to an HF receiver. Usually the noise in the receiver is set by the atmospheric noise the antenna picks up, not by the noise factor of the receiver. (On the higher HF bands, 15m and 10m, this may not always be the case) The same would apply for the 2m converter. Unless it is designed very well its contribution to the noise at the antenna of the receiver would probably mask the noise factor of the receiver itself.

If you could kill the power to the converter you could probably test for this by just killing the power and seeing what happens to the noise out of the receiver speaker. If it goes down, then the noise factor of the receiver is irrelevant. If it doesn't change then the converter is contributing less noise than the receiver itself.

If turning off the AGC causes less noise output then my first guess would be to look at what "turning off the AGC" is actually doing. Is it actually breaking the AGC loop so the AGC inputs to the CA3053 amps are left floating? Or does turning off the AGC actually mean putting a fixed bias on the CA3053's? Either case could potentially cause the gain of the CA3053's to actually go down with the AGC turned off and that might be what is going on.

Can you actually monitor the AGC loop to see what happens to the AGC voltage when the AGC is turned off?

Hi Andrew, don't you mean "grab a copy of 'The Art of Electronics' by Paul Horowitz and Winfield Hill"? As far as I can tell H & H never wrote 'The Art of Engineering'.

You made some halfway good points in the age old "me Technician you Engineer" argument, but you lost credibility when you recommended a book that doesn't exsist. Attention to detail, Engineers do, Technicians don't :-).

If you can't help, don't hinder.

This had nothing to do with the orginal question-sorry.

tim gorman <tgorman2@cox.net> wrote:

: A block diagram would be helpful. Do you know if the AGC is being derived
: from the audio chain or from a sampling circuit in the IF chain?

The AGC is derived sampling the RF level at the last IF. In the same point,
(using another diode, capacitor, etc.) there is the AM detector. The same RF
signal go to a diode balanced modulator along with BFO signal for CW and SSB
and to the input of FM IF amplifier (TA7061AP).

: Where are you turning off the AGC? In the FR-101? It sounds like you have a
: frequency converter feeding an HF receiver with an FM position. Is that
: correct? Could you just as easily tune in 2-m SSB as well as 2-m FM?

I have a FR-101 with the onboard 2m converter. Yes, I could tune 2m SSB but
it's difficult to find SSB on 2m here usually so I didn't any test. The FR-101
is CW/SSB/AM/Narrow AM in segments of the HF range, plus you could buy (as a
option) a onboard 2m converter, a onboard 6m converter and a onboard FM
detector. I have all boards installed, so I eventually could use FM on
HF as well as 2m or 6m.

: If you could kill the power to the converter you could probably test for
: this by just killing the power and seeing what happens to the noise out of
: the receiver speaker. If it goes down, then the noise factor of the
: receiver is irrelevant. If it doesn't change then the converter is
: contributing less noise than the receiver itself.

Turning on the 2m converter don't seem to change noise level, while instead
turning on the 6m converter seems to double the noise. Maybe it needs
realigning, I never use it so I don't know if it's working well.

: If turning off the AGC causes less noise output then my first guess would be
: to look at what "turning off the AGC" is actually doing. Is it actually

The AGC line is derived from a fixed voltage using a 9V zener, then the RF
GAIN pot permit to divide this voltage from 100% to ground and feed it (trough
a resistor) to the first RF amplifier of the HF receiver (a DG FET) as well as
the first RF amplifier of the 2m converter, and the same for 6m converter.
It is also fed to the last but one CA3053. Other amplifiers are fixed gain
I suppose.
Everything in the receiver needs to reduce gain, lower this voltage by more
or less shorting it to ground.
For instance, the standby button shorts it to ground, silencing the receiver
completely. The RF level at the last IF instead reduce it by means of common
emitter transistor: the AGC voltage from zener at the collector and the
rectified and filtered IF at the base.
When you disable AGC, you disconnect the collector of this transistor, thus

the signal is let alone to the level adjusted with RF gain pot (normally at maximum, so it is 9V).

By looking closer at the AGC circuits, there is RF AGC also in the 2m
and 6m converters. However, the AGC involves not all amplifiers in this
receiver, just the first and the last but one. I often see different
configurations in receivers, where every amplifier is controlled.
Maybe they thought it would suffice.

: Likely a test point that is not marked on the board. I don't have
: a print handy.

I had calibrate it for the minimum voltmeter reading, because it appears that
the signal is negative over a positive DC bias, supplied by the JFET.
Probably there is another point where the signal is positive, anyway it
should be the same.

: Having experimented with recievers since before EE school and still
: many decades later I find it challenging. Always looking for and at
: new ideas.

I have read very interesting articles on QEX (by downloading them in PDF
format from the site) following back the chain of cross references starting
from "A software defined radio for the masses" to the R1 and R2.

Every designer has his own ideas about AGC, dynamic range, et all. Often
very different. While I never (as now) tried to design a receiver, I want
to carefully understand the reasons behind every implementation. So I could
build my own opinion and in future choose what I think better for a receiver
project.

Anther interesting argument is LO: DDS, PLL or DDS+PLL?

The various "free flea" ham events that pop up here ins S FL are well
attended. They are short and sweet events opening at the crack of
dawn and ending by noon. Stuff for sale is a mix of old radios
from the 50's through the 90's (with a few WWII boat anchors here
and there), lots of computer crap (who wants pre-pentium stuff these
days?), and a few tube vendors. Also the usual guys just cleaning
out their junk boxes. Why pay to go to a big ham fest when you
can show up at a freebee? I usually don't find any real big bargains,
but I do bump into old friends, chew the fat, and usually take home
some needed parts for a project.

Maybe the flea markets at the big
shows are lean because all the sellers have dumped their stuff at
the free fleas? It is a pain to have to load up, set up, hang around
for two long days and then pack it all back in and go home. With
the free fleas you just open your trunk throw a blanket on the floor
or open up a folding table or two. 5 or 6 hours later, (not too
long a drag) you pack it up and go home. You'll take less stuff
to sell, and maybe have to go to a few free fleas to get rid of it all
but somehow it seems like less wear and tear on the old body.

I still like to go to one big hamfest a year though, just to see what
the big vendors have come up with.

Often not every amplifier needs to be controlled. It's a matter of
van the overall gain change be achieved with fewest control points.

>

Generally will be. What I have seen in some cases is where the no
signal resting point for gain control bias voltage is not correct and
the gain can go up a bit before going down. Often seen on oder
recievers where the large part of the radio is discrete devices
and the various setpoints have drifited from age or componenet
changes.

>: Having experimented with recievers since before EE school and still
>: many decades later I find it challenging. Always looking for and at
>: new ideas.
>
>I have read very interesting articles on QEX (by downloading them in PDF
>format from the site) following back the chain of cross references starting
>from "A software defined radio for the masses" to the R1 and R2.

I've build R1, R2, MiniR2. I happen to like the miniR2 and use on
with the matching T2 in 6m as my highest performing RX. Highest
performing in this case is best dynamic range and lowest noise.

SDR is an extension of that work. However since most of the digital
work is done at low IF (under 50khz) or at baseband all of the
frontend, filter and IF issues remain though the tradeoffs may be
different.

>Every designer has his own ideas about AGC, dynamic range, et all. Often
>very different. While I never (as now) tried to design a receiver, I want
>to carefully understand the reasons behind every implementation. So I could
>build my own opinion and in future choose what I think better for a receiver
>project.

Very true. What was considered best in class for 1960, 1970, 1980
and so on has changed considerably. However it's possible to
use older topologies with newer devices and obtain perfomance
unattainable back then. What is easiest to build and make perform
is usually a low gain approach using amplifers that do not overload
easily to get a balanced dynamic range and noise figure. I've seen
too many chase for a high gain for sensitivity at low HF only to
be overloaded with man made and atmospheric noise.

A good example of a strong staple topology is the Elecraft K2. A
very solid single conversion with medium high IF transceiver. The
basic design topology is 25 years old (look up Progressive RX,
QST) but, it's well executed using current tech parts. The manual
is available on line and worth reading and reviewing.

>Another interesting argument is LO: DDS, PLL or DDS+PLL?

I use Analog with premix for lowest close in noise. Though I
also have a DDS with PLL tracking filter and a straight PLL
system that has proven satisfactory at my favorite band (6M).
In each case considerable care was taken to well shield and
filter the signals used while using the best techniques. Executed
with care and with an eye for how it fits into the system all work
well. Of those (opinion follows) I find DDS has agility and stability
with the very noticeable tradeoff for spurious outputs. Due to that
I prefer to restrict raw DDS to narrow band systems or clean
them up with a tracking PLL. The cost is power, and great
care in shielding as the various oscillators and the concurrent
need for a microprocessor to do the translation of knobs, buttons
and tuning displays into the digital control for DDS can contribute
to a lot of undesired signals (birdies).

So the whole subject of the LO system can be as complex as the
rest of the reciever and be a significant factor in it's total
performance.

Rob,

IF you desire to build a solid-state RF amplifier -- it will be for
education / build desire -- rather an economics (in other words -- a used
Ameritron/MFJ ALS-600 (with 4 MOSFETs) is often much cheaper.

It is advisable at 500/600 watt and greater -- that 24/28 VDC or 48/50 VDC
RF transistors be used -- lighter gauge wire - less amperage from power
supplies.

Next read all that you can about Helge Granberg, K7ES(sk) -- Finland's
version of Art Collins

Ok, have you checked the Dual Gate FET to insure that the bias supplied by the RF gain control puts the device at maximum gain when the AGC is off?

Dual Gate FET's have transducer gain curves that are peaked curves. Depending upon the Gate 2 voltage, the transducer gain can actually go down as the Gate1 to Source voltage goes up.

I would still be interested in knowing *exactly* what the AGC voltage on the gate of the DGFET is for 1) AGC on, no signal, RF gain wide open, and 2) AGC off, no signal, RF gain wide open. It would also be interesting to know what the Gate 1 bias voltage is for each state as well.

I'll bet you'll find an interesting interaction between the bias voltages and the actual stage gain as the controls are manipulated.

Tim,

Your hitting the specifics of what I refered to earlier. I'll repeat
it for emphasis.

What I have seen in some cases is where the no
signal resting point for gain control bias voltage is not correct and
the gain can go up a bit before going down. Often seen on oder
recievers where the large part of the radio is discrete devices
and the various setpoints have drifted from age or componenet
changes.

I have seen this on older radios where parts have been replaced or
the original parts used were at opposing ends of the allowable
tolerence. Occasionally a part like a zener doide can drift form
heating. The end result is the full gain voltage can be off or full
gain for a single stage can be off (high or low from optimum).
In one case it was a mechanical switch (agc/manual) causing
difficulty (leakage path). Other suspect components seen in
Japanese built radios are those commonly used ceramic disk
caps for bypasses, they can and do go leaky(high resistance),
or short and I've even seen microphonic. I have a reciever I
repaired where the DGfet developed a substrate to gate2 short
which casued all manner of unusual problems.

The worst case by far was one that the agc bias point had drifted
a bit high. When on manual agc the RX was hot. When agc was
enabled the RX sensitvity would drop noticeably. The problem
was the higher agc bias point had the IF and RF running harder and
producing more noise and when agc was turned on it would see the
noise and pull the agc voltage. That sounds ok save for the front
end was more agc sensitivve than the overbiased IF and the front
end would loose gain faster (it was 2 jfets cascode) rendering the
reciever less sensitive. The fix was repairing the internal voltage
regulator that fed 9V to most of the circuits (it was running at 11v
due to open zener).

Just a few examples of what can occur. I havent even gone into the
golden screwdriver problems when pots are tweeked for "more".

>I'll bet you'll find an interesting interaction between the bias voltages
>and the actual stage gain as the controls are manipulated.

I'd be inclined to agree.

I stumbled on to a hand full of old/new parts that I will never use which consist of,

3 ea Millen 39005 universal joint couplings for 1/4 " shafts.

2 ea right angled geared drives that terminate with 2 1/2 " X 1/4" shafts. I believe these to be National parts.

1 ea 5 & 3/4" X 1/8 " flex shaft (can bet cut to length) that has an isolated coupling on each end that will accept 1/4 " shafts. I also believe this to be National part.

These are quality items, probably 30 - 40 years old. I'll send any place in the continental US for $20. Rob Mills

4121. 7854 Tube/Motorola 9TS136401 Schematic?

Hello all. I'm looking for a circuit schematic to use this tube on 6 meters and 2 meters. So far I'm stumped. I think that this tube was used in some early commercial tansceivers, but I'm not 100% sure. Also would like to know if this is same tube as Motorola P/N 9TS136401
It is the same size as a 5894 but with much thicker plate pins as well as amuch beefier plate structure with an extra fin in the structure for cooling. Even the glass is thicker.I'd even consider buying the final section that used this tube. Any help at all would be greatly appreciated. Thanks and 73

If you really want to be rigorous about it, you could set up some kind of logging system, perhaps with an A/D converter and computer connected to a reference antenna and simple detector, to measure and log signal strengths over a long period of time. The tough part would probably be deciding what kind of filter to precede it with; maybe something typical of what you expect to use in a real receiver. Then you could do a statistical analysis on the logged signal strengths. Whether or not that's worth while would be up to you -- it would at least certainly make an interesting article. Or, you could build something and put a coarse step attenuator at the front end, noting how much attenuation you have to apply when operating in order to keep the spurs down.

Very nearly 30 years ago, I was looking into "feed forward" circuits, a technique developed by someone at Tektronix for ultra-low distortion amplification. It turns out that the topology of the MC1350 is similar to what's needed, and a feed forward amplifier can be made from one plus just a few external components. But even by then, I'd learned that it's risky to use components for other than their intended purpose. So I collected 8 or 10 samples from various vendors (the part was widely sold then), and opened them up. Those in cans were easy, using a little can opener that worked like a tubing cutter. Some of the plastic DIP ones were more difficult, but one of the labs at Tek was able to dissolve the plastic while leaving the chip intact. Then I examined them carefully with an inspection microscope. Here's what I found:

1. There were at least three very different designs. The chip size of the largest was several times that of the smallest.
2. Some designs were inherently better balanced than others. Some had resistive "cross unders" where traces cross, which weren't the same on both sides of the circuit.

Based on this, I decided it was too risky to make a design based on that part number, since a vendor could change chip suppliers or designs without notice.

Interestingly, about six months later, I got a call from the component engineering group asking if I still had the chips. It seems that one or more of the vendors supplying that part (which was used for other applications at Tek) had changed their design, causing failure of some products and the shutting down of their production lines. Tek was big enough that vendors were often required to give advance notice before such changes, but they hadn't given any notice in this case.

I'm bringing this up because I'm hearing the MC1350 being spoken of as though all are the same. It wouldn't surprise me if, after all these years, they're now all being made with one design from one foundry. But those ones in your junk box might be way more different than you think.

This is almost certainly true of just about any IC.

I assume that you do not have the companion AM-65 audio amplifier?
Shame, because internal to that unit is a power supply (don't remember the numbers now) that allowed you to operate the AM-65/RT-70 combo from 6, 12 or 24 volts depending on the power supply used. The usually supplied unit used 24 volts (Korean War American military standard elec system). If you can't get the 12 volt version, modification instructions can be found in a 73 Magazine article called
"New Orders for the R-108" which was a companion receiver for the big brother of the RT-70, the RT-68. R-108 used the same series of plug in internal power supplies that the AM-65 did.
There was also a magazine article in the now defunct as well Ham Radio mag titled "Get on Six Meters-The Easy Way". It dealt with a manpack 6 channel radio of Canadian ancestry that also needed 90 Volts. I have the entire run of that magazine from 1969 to 1990 on cd. If I can figure out how to extract the stuff off the disk, I'll email it to you. Now, the fee for such information.....
You will regale me with tales of operation and modification of aforementioned Olive Drab garbed electronic equipment!!! I'll email you later from my own account so that you will get my real email address, or you can use the arrl reflector. 73

Roy,

That is my engineering experience as well. At the time I did my
testing I had Motorola, National and Hitachi parts Some fairly current
date codes and a few from early 80s and and while the general
behavour was similar I noted differences in gain, overall noise
and DC balance as well. The noise increase was enough to
be noteable in a particular case but on analysis understandable
and to be expected.

Then again I date back to when the Fairchild UA703 was a
breakthrough gain block for RF.

4127. Book recommendation please

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-08-28 04:11:38 UTC
From: David <websales@orbitcoms.com>
Message-ID: <_1uIg.19044$rP1.12765@news-server.bigpond.net.au>
Source record: 10828

Anyone recommend a "decent" book that would cover oscillators, small signal RF amps and matching techniques sufficiently to enable a novice to start experimenting with circuits and have enough detail in the text to tweak the circuits to get them running properly ?

I have purchased numerous books and cannot yet find one that is capable of giving me enough clear information to do something useful (Or more to the point, I cannot seem to get onto the same wavelength as these guys).

My predominant interest is VHF (150MHz). Low power (1 Watt or less), no valves, no requirement to use rf transformers for matching through the entire circuit.

Someone mentioned an analog design book a while ago and that may have been appropriate and I could not remember the title. I thought it was "The art and science of analog circuit design" so I purchased that book and was disappointed to find it was full more of anecdotes of a bunch of well seasoned engineers along with some handy tips.

Thanks

David

"Experimental Methods in RF Design" by Hayward, Campbell, and Larkin, available from the ARRL, would be a good place to start. It's the successor to the classic "Solid-State Design for the Radio Amateur" from back in 1977.

If you can find copies of Doug Demaw's "Design notebook" and "QRP notebook", there's some good reading there as well. Not as advanced as "Experimental Methods" but perhaps a bit more accessible.

Buying a bunch of back issues of QRPp might also be helpful. In a lot of the articles which discuss QRP receiver and transmitters, the authors go into detail about their own particular circuit preferences, tweaks, construction and debugging techniques, etc.

For a slightly deeper background, I'd recommend "Troubleshooting Analog Circuits" by Robert Pease. It's not specific to RF but is full of useful tricks and ideas.

Dave,

I do have EMIRFD but find almost all the circuits are based around rf transformers for matching and most of them are low frequency (3MHz etc).

Regards

David

For the primary matching stuff, that's true.

You might want to look at the sections on crystal filters... if I recall properly, there are some filter arrangements which use an LC match at one or both ends.

You might want to dig into the ARRL books on UHF and microwave, and perhaps a copy of the old ARRL VHF manual (out of print but available used).

I think, though, that you're probably out on the bleeding edge of amateur experimentation. Not a lot of people are homebrewing VHF gear these days, so there may not be a single book which goes into the sort of circuitry you're interested in with an eye towards from-scratch design work.

I'm looking right now at the ARRL VHF Manual's description of a 2-meter portable design, circa 1972 - AM transmitter and superregenerative receiver. It's all solid-state - no tubes. However, as with most such designs I've seen, it has quite a few transformers in it - typically part of single- or double-tuned resonant circuits between the stages. The design seems to do both the tuned filtering, and the impedance matching with the same components - not an unreasonable approach. The oscillator strips in a commercially-built 2-meter FM repeater's transmitter and receiver I tore apart recently use a similar approach.

If you really want a transformerless design, I'm sure it can be done, but the necessary L/T/pi matches may end up being more difficult to design, and trickier to tune than a more conventional transformer-based design.

Dave,

At present I have an issue with a Butler emitter follower oscillator at 150MHz.

I have Matthy's "Crystal Oscillator Circuits" and Randall Rhea's "Oscillator design and computer simulation" books. Also EMIRFD, "Introduction to RF design by Wes Hayward", "Complete Wireless design by Sayre", "RF design by Boswick", ARRL handbook, VHF/UHF handbook and a few more fundamental electronics and antenna books but try as I might I just cannot seem to ever extract enough information from all these books combined to get a useful result.

The Butler design I am looking at has a circuit for 100MHz. I assume this would be close enough to use the same typology but adjust the tuning components for 150MHz.

The book mentions tuning near by not at resonance. I have no idea how far "near" is and should it be above or below resonance or does it not matter.

He then states the holder capacitance of the crystal is 4.2pF and that he tunes this capacitance out with a 410nH inductor. If I calculate this, I get 600nH inductor to tune out 4.2pF at 100MHz. Why would he use 410nH instead of the larger value ? No mention in the text.

He mentions that tuning "near" resonance is achieved with L and Cap from base to emitter. He shows a 8-15pF cap. If I assume the trimmer set about half way at say 12pF and use his value of L of 120nH then the circuit is actually tuned to 132MHz. (I am not sure if this 30% higher frequency is what e really means by "near resonance". He also does not take into account the Base emitter capacitance or the cap to ground of the c-tap. Is the assumption that these do not matter ?

I made the circuit with changes in values to try to achieve 150MHz and it worked but had extremely critical tuning (very small adjustment in the tuning C stopped the oscillation). It also appeared to run slightly lower than the stamped marking on the crystal so I assume the either the crystal is cut 100ppm lower for parallel mode or I have not tuned out enough Co or something ?
This is where I now need more detail to understand why the circuit behaves like this and what to do to fix it.

I would also like to change the bias current as the 19mA current draw is a lot for my application. 5mA would be good but without properly understanding how to calculate Rout of the emitter follower, I am not sure the resistance is getting too high toi drive the crystal.

I have tried common base butler designs and they seemed to be easier to
get going and understand but several text point out this design is prone
to have instabilities and small ranges of inductance in the tuned tank
that they will run over.

I need to find some text that would cover issues like this but not so
deep mathematically that I need a degree to use the math.

Thanks

It sounds like some of the HP or Motorola app notes might be helpful for this. Maybe someone can suggest some specific ones.

Up to around 200mhz thats not a big issue if properly scaled and the
right ferrite used.

I've used a lot of ideas from that book at 6 and 2m. The book list
presented is one I'd have suggested and added the venerable handbook
both current and a few older copies.

Thanks for the feedback.

I do not have a ready supply of ferrite cores and do not really want to
wind coils.
I have surface mountable air fixed coils that provide Q > 100 that I
expect should be suitable for most applications and use of trimmer
capacitors.

The only high frequency crystal oscillator I could find in the EMRFD
(100MHz) is page 4.15 which is a common base butler. I understand these
suffer parasitic effects, the tank is only effective for a limited range
of inductance. The butler emitter follower is offered as a more superior
typology but this circuit is not found in this book.
The circuit values in his example are incorrect as the 25nH inductor in
the tank requires over 100pF to resonate at 100MHz. The circuit shown
has a net capacitance of around 40pF ?
There is very little design information given with respect to ratio of
the C-Tap or emitter bias.
I also have his book "Introduction to Radio Frequency design". This does
go into more depth but is centred mainly around colpitts oscillators
(not good for harmonic crystal oscillators).

Hi David,

I've read through the rest of the posts, and in general I think you have a decent selection of books. The couple I'd add:

"RF Oscillator Circuit Analysis and Design with Breadboard Experiments" by John Plastonek -- Which is no longer in print, but I could probably scan it in one of these days if you can't find a copy kicking around (I've made active efforts to find this Plastonek guy to ask him about this, and he seems to have dropped off the face of the planet). His oscillator circuits go up to ~100MHz, and he has some discussion as to why you might prefer one oscillator topology over another.

"Build Your Own Low-Power Transmitters: Projects for the Electronics Experimenter" by Graf & Sheets (you can preview it on-line at Amazon.com). He has plans in there for transmitters at pretty much all frequency from LF-SHF, and although I haven't build anything in it myself :-), I've heard from other people that the transmitters really do work.

"Practical RF Design Manual" by DeMaw -- Probably overlaps a lot of the of DeMaw books; now distributed by MFJ.

BTW, I wouldn't be so quick to give up on RF transformers and matching -- any RF circuit with active components in it is going to require some amount of matching, and while at times you can get away without formally considering it, doing so often gives up power or robustness. (I know it's a little disheartening to open up a commercial radio and see that they managed to achileve something like a stereo FM receiver all in 7 transistors and no RF transformers, but such designs are the evolutionary results of a lot of people spending a lot of time trying to cost minimize a product that's produced in the millions. And keep in mind that something like a cell phone today requires over 100 man years to design...)

Finally, don't write off books such as "The Art and Science of Analog Circuit Design" -- it's a great example of one of those books that has a lot of great advice in it, but until you've hit your head on the wall a few thousand times encountering the particular problems the authors have, its value isn't apparent. The sort of "tweaking" advice you're looking for with RF circuits is precisely what TAaSoACD is trying to provide... just more to folks building op-amps & data converters than RF circuit.

Built as described, it works. However the 25nH is an approximation
as distributed C and also lead lengths add significantly. Mine tuned
with 33ohms substituted for the crystal from 93 to 122mhz.

>There is very little design information given with respect to ratio of
>the C-Tap or emitter bias.

Read the test as the concepts are outlined rather than how to design
xyz circuit in cookbook fashon. If you need help, the easy way is
to calculate the reactances at the shown frequency and then using
those numbers scale for the desired frequency. The bias point would
be the same at any frequency for a given transistor and power.

>I also have his book "Introduction to Radio Frequency design". This does
>go into more depth but is centred mainly around colpitts oscillators
>(not good for harmonic crystal oscillators).

In general oscillators in the >20mhz range are harmonic or overtone
designs and more subject to parasitic effects. I've bult the 100mhz
design and it worked fine for me within the limits of the crystal used
though after a x4 multiplication the thermal drift was unacceptable
and the crystal was the first order contributor. The oscillator
otherwise behaved well.

My solution for the whole mess was a lower frequency osc
and using low order harmonics. The lower frequency crystale proved

both less fussy to oscilate and more stable in fundemental mode.
Note: I was interested in sufficient stability to copy SSB at ~1296mhz
so even a few dozen Hz drift is noticeable..

4137. Beginner Radio w/o using air variable cap???

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-08-28 21:42:55 UTC
From: SparkySKO <sparkysko@gmail.com>
Message-ID: <1156801375.566432.201790@m73g2000cwd.googlegroups.com>
Source record: 10838

Hello All,

[Basically this says, are there any practical alternatives to an air variable capacitor that a beginner can use in building his first receiver radio?]

I'm interested in getting my feet wet in building a receiver, but don't want to buy a 'kit'. I'd like to build a radio that has a knob I can somewhat tune it with. I've been really looking at regenerative radios and superheterodynes, although a simple radio is more important than how well it really performs.

One common theme in almost every 'simple' radio design I can find, is that they *ALL* use Air variable capacitors. While I'm sure these were everywhere 20 years ago, going to every major electronics supply house in Portland, Oregon has yielded me only with small trimmer capacitors, which AFAIK, will not do for a 'tuner'. I'm aware I can order online for about 10-20$ and purchase an air variable, but I'd like to see if any of you have any suggestions on what might work as an alternative?

Varactor diode seemed like a neat idea, although I guess they suffer from temperature fading. Would this make it impratical for a shortwave or AM receiver? Can you even make a regenerative radio out of a varactor? (Actually, I'll try ghetto rigging a red LED for a varactor, since I don't really care about it being nicely linear, I just want something with a knob that does something!).

Can anyone recommend any type of reasonably simple radio (simple mostly as in reasonably low parts count, i don't need an LCD readout) that could possibly be done with parts that can be had at a reasonably stocked electronics store. (Much more inventory than Fry's). A knob is important, I don't want to build one of those ghetto radios with the coil and a metal bead that I slide along the coil to 'tune' it. Any other way to use a potentiometer to tune a radio?

If you want to build a radio circuit without much circuitry you really
have to put up with either a variable cap or a variable coil. I'd say
you either have to scrounge something or buy one -- they're really not
that spendy.

Yes, you can go the varactor route, and folks have made it work well.
But you have to add more components, it'll never be the same, and you'll
have to tinker with it to keep it from drifting all over the place. For

a 1st-time radio it may not be a bad thing, but after that I'd go with a real variable element.

As far as your complaints about 'ghetto' radios -- your ability to build a high-quality, good looking tunable element is a matter of the talent that you were born with and the effort you take to use it. If you want to build something without many components then you're going to need to work at it anyway.

Having said that I wouldn't build -- I'd buy. Have you checked with Cascade Surplus Electronics in North Portland? It's been ages since I've been in there, so I can't guarantee anything. You may also want to try R 5-D 3 Electronic Surplus out in Southeast. He's got lots of old stuff there, if he doesn't have a variable cap he'll have some piece of crud that you can buy and harvest the caps.

After those two, consider going to yard and garage sales, buying old radios, and tearing out their capacitors. Stereo tuners from the 70's and 80's are best -- if it's big and has a knob, chances are it has a cap. If it receives FM and it's big and has a knob , chances are the cap will be a good size for shortwave. You may even find that it has a cap with a built-in reduction drive which is cool if you want to tune in CW.

Good luck.

I'd try R5D3 first, then see if I could find something worth
cannibalizing at Cascade (note new address) or Wacky
Willy's (lots of junk, but you never know...). Then I'd hit the
various thrift stores and see if I could find an old FM tuner.

Are there any ham radio swap meets coming up?

If you go to R5D3, they really are on a residential side street
out in the middle of nowhere.

The parts are out there. Go get them!

From what I understand so far the bias should should not necessarily be the same and the capacitors will not scale as suggested.

The ESR of the crystal would be different for different overtone crystals so therefore the bias should change to provide correct drive and C to ground on the C-Tap would also need to change. According to Matthy the Cap to ground should be 0.5 to 1 x ESR and emitter drive impedance less than ESR. Or have I misinterpreted something here ?

I am also unsure of whether the tank should be tuned above or below resonance. Rhea's book suggests the tank should be capacitive at Fo indicating the tank itself would be tuned above the operating frequency.

I would like to learn more about the Butler emitter follower crystal oscillator.

If I ask the specific questions about this typology and someone gives me an answer, where did they obtain this information. Have they learned by just playing with the circuit in a hit and miss fashion or have they first obtained fundamental information from some text and using what they have learnt then played with the circuit. If so, what would this text be ?

If Ro = Rsource/(beta+1), is Rsource in the oscillator case of the emitter follower Rp of the coil in parallel with the bias resistance or does it also include (Rphi+RE) x Beta. Is Beta used here an approximation calculate by Ft/F ?

For TWO BUCKS I bought a whole box full of cheapie "transistor radios"
from a church rummage sale a few weeks ago (most were about the size
of a man's wallet, but a few were about the size of a thick book), and

ALL OF THEM HAD AN AIR-VARIABLE TUNING CAPACITOR!

Don't fight a battle you don't need to fight; just tear up an old
"transistor radio"!

(Now the NEWER transistor radios -- the kind you buy at WalMart for
a buck each that have a "push to tune to the next station" button --
do NOT have air-variable capacitors, but the OLDER ones do!)

I am looking to purchase 1 or 2 Cobra 148 GTL units that were made in
the Philippines.
If you have or know of someone that has please contact me at
copdoc1@optonline.net
Thank You
Peter

Varying the inductance by moving a core in and out of the coil works
just as well, and is quite easy to make at home.

Leon

> to tinker with it to keep it from drifting all over the place.

Varactors are not that tough, and don't mistake the "never be the same". Good varactor rigs are much more pleasant than anything with a variable cap. (Although there are plenty of bad varactor designs out there!) Yes, sometimes there are a couple more components, but not many more. It does take some work to get a varactor oscillator close to drift-free, but five minutes with a calculator will get you close enough for SWLing. Oh by the way, getting a capacitor oscillator close to drift free can be a challenge, especially if you don't have hard-to-get air inductors, and microphonics in that case can be a challenge, too. The larger size of the variable cap/air inductor makes mechanical construction details a lot more important. There's really no free lunch.

Varactors do have some temperature coefficient, and they are often coupled with toroid inductors, which also have some considerable temperature coefficient. Most of the designs you see out there are for CW rigs in the ham bands, where temperature stability is extremely important. The maze of capacitors around the varactor are there to balance the temperature coefficients. Usually there is a polystyrene capacitor which has a temperature coefficient opposite to the toroid and varactor, but you can never get exactly the right value for that, so it is a question of getting the right combination of positive and negative temperature coefficients AND the right value of capacitance. For AM in the broadcast band, you can probably come close enough with one or two capacitors. For a rig with a 200 Hz CW filter at 15 meters, it can be a real bear keeping the frequency to within the 0.0001% that you need for comfortable operation.

That being said, it is undoubtedly easier to use a variable cap, and caps can be cannabalized from old radios easily and cheaply. Leon also mentions the possibility of making a variable inductor. Actually, from time to time articles have appeared about making variable caps, too. In either case, though, you will need considerable mechanical skills.

One thing that makes projects hard, especially your first projects, is this idea that you need exactly the right part. With a little help from your trusty calculator, you can play pretty fast and loose with parts values in most projects. In the case of a tuning cap, if you can find something on the right planet it typically isn't too tough to make adjustments to accomodate the different part. Study your circuit and understand what each part is doing, especially around the tuning circuits. It is usually pretty

simple to make some adjustments, especially if, as you suggest, getting some precise tuning range isn't critical.

..

The DC bias would be unchanged. The feedback required may need
to be altered but thats a product of frequency and transistor(or fet)
gain at the target frequency and any change in overtone used.

In short if the circuit shown uses a 100mhz crystal in a 7th overtone
mode it will scale if a 89mhz 7th overtone crystal is used. Usually
for a narrow range of frequencies like that the ERS varies but not
greatly. This does not cover the difference between good quality
crystal and poor quality crystals, If you going to use poor quality
crystals there may be other issues to investigate as well.

>I am also unsure of whether the tank should be tuned above or below
>resonance. Rhea's book suggests the tank should be capacitive at Fo
>indicating the tank itself would be tuned above the operating frequency.

Believe it or not, doesn't matter. You'll build it and then have to
tune it for proper oscillation. At around 100mhz the circuit
parasitics such as coil construction, PC board trace capacitance
and inductance, transistor characteristics, transistor, coil and
capactior lead length are all in the mix.

>I would like to learn more about the Butler emitter follower crystal

>text be ?

Generally I try to avoid high order oscilators(overtone) as stability
and the need for being tuned doesn't suit my needs.

I've never seen a in depth analysis in any one book. I apply
my EE training plus 30+ years of theory vs what really happens
and go from there. Sometimes being an engineer is really more like
science where you observe and build or search out theory to explain
the observed behavour, or you break out the diddle stick and adjust
it and move on to bigger problems.

>If Ro = Rsource/(beta+1), is Rsource in the oscillator case of the
>emitter follower Rp of the coil in parallel with the bias resistance

>approximation calculate by Ft/F ?

Thats all first order rule of thumb. However, are you trying to build
one working oscillator or flog it to death? I say that as I've found
it to be both less than an exact science and that accurate to more
than 3 decimal places is excess for operation. For one oscillator
it is both easy and practical to dead bug it and see if it meets
your needs. If you going to build in quantity something using it
that is a whole different set of issues.

This homebrew 10-600pF book-shaped air variable has knob tuning:
http://www.leradiodisophie.it/CV-libro.html

Wind a simple coil, add a diode and audio amplification -
see what you can hear.

It's the lying that bothers most of us, I bought a radio from him and it smoked when I plugged it in, upon examination, I found it was NO WHERE NEAR what he described, he used photos that didn't show the imperfections and outright lied about the ownership. I know several people who have sold gear to him (using his gottahaveit1995 name) only to see radio-mart sell it a week later, claiming it came from his personal collection and had owned it for years!! Then he lies about the condition of it, not to mention that he shill bids on his gear using the above mentioned gottahaveit1995 name. This asshole needs to be run off ebay, because of how he screws unsuspecting bidders!!

I finally caved in and cannibalized a radio. 8$ at big lots (heck they even had one for 4$, but this one had a bigger 'knob'). Sure enough, a variable cap (plastic spacers in between the plates).

Oh, A local!
Okay,I'mma spill the beans,and 'leak' my hidden treasure trove..
Check out "R5D3 Electronic Surplus" out in Milwaukie,off of Johnson
Creek road.
He's got *tons* of tubes,and lots of other useful parts for cheap.
Got a couple bins/boxes full of variable caps and all that stuff.

Bob's a cool guy. Tell him "that young punk" sent ya. ;-)

4152. Re: Book recommendation please

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-08-29 20:41:09 UTC
From: David <websales@orbitcoms.com>
Message-ID: <FD1Jg.19969$rP1.8517@news-server.bigpond.net.au>
Source record: 10753

Thanks for the information.

The book example uses a 5th OT 100MHz crystal. My application uses a 7th OT 151 MHz crystal.

I suspect the ESR jumps from around 60-70 in the 5th OT to a max. of 120R for the 7th OT.

Something I find a little confusing though in in Matthys book at the beginning he explains that in series mode, the lower the impedances driving and loading the crystal - the better as this ensures the crystal has maximum control of the feedback path.

But during his explanation of the butler emitter follower, he mentions the load cannot be "too" small and suggests optimal load of 1/2 to 1 x ESR. Can you shed some light on this for me please.

I realise another option is to build a 3rd OT oscillator followed by a tripler and filtering but I find when I do this that I have trouble getting rid of harmonics. Also each tank circuit ends up adding lots of cost to the circuit as I usually use a fixed air-wound SMD format coil and SMD trimmer cap and these are expensive.

Another option was I could use a PLL as I have a heap of the LMX1602. Then the trouble is that the microcontroller overhead goes.(Having to set frequency each time the system boots). I also looked at other PLL ICs like the motorola devices that can be pre-programmed with pin settings but these seem to be hard to obtain now.

Thanks again. I appreciate the time people have taken to consider my questions and provide me with some valuable insight that I have not yet gained from experience. (I suppose that is the power of such a forum as this anyway).

regards

David

4153. Hi-Q Ceramic Caps?

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-08-29 21:57:19 UTC
From: SparkySKO <sparkysko@gmail.com>
Message-ID: <1156888639.427999.12080@p79g2000cwp.googlegroups.com>
Source record: 10754

Hello All!

Bare with me, I'm a newbie.

I'm looking into building the Radio Shack Special

http://www.electronics-lab.com/projects/rf/007/

And looking through the parts list, I see that he references using Hi-Q Ceramic Capacitors. This radio is for FM, so 90-110mhz.

I have a bunch of normal ceramic capacitors, but no hi-q capacitors. Is there really much of a difference between the two, or am I likely to fail if I don't use them? I'd hate to solder all this onto a board, and risk messing up the board when removing them.

Any advice on the difference between them would be helpful. I'm guessing they oscillate better, or at higher frequencies.

I dont consider that a huge jump, considering the amount of tolereance
there is in that kind of thing.

>Something I find a little confusing though in in Matthys book at the
>beginning he explains that in series mode, the lower the impedances
>driving and loading the crystal - the better as this ensures the crystal

if the crystal feedbak path loads the crystal too greatly the problems
of mode jumping and poor starting are present.

>But during his explanation of the butler emitter follower, he mentions
>the load cannot be "too" small and suggests optimal load of 1/2 to 1 x
>ESR. Can you shed some light on this for me please.

too low the osc will not start (low effective gain) and too high
allows for possible mode shifts.

>I realise another option is to build a 3rd OT oscillator followed by
>a tripler and filtering but I find when I do this that I have trouble
>getting rid of harmonics. Also each tank circuit ends up adding lots of
>cost to the circuit as I usually use a fixed air-wound SMD format coil
>and SMD trimmer cap and these are expensive.

I would think using double tuned and properly coupled the undesired
harmonics should easily be more than 70db down. Requires some care in
layout and grounding.

>Another option was I could use a PLL as I have a heap of the LMX1602.
>Then the trouble is that the microcontroller overhead goes.(Having to
>set frequency each time the system boots). I also looked at other PLL
>ICs like the motorola devices that can be pre-programmed with pin
>settings but these seem to be hard to obtain now.

Those headaches and also sidebands that are not well surpressed
if care is not taken make it potentially worse than 3rd OT and

tripler.

build and test is my suggestion.

Allison

For the 5 pF and 15 pF capacitors, use only NPO (C0G) ceramic capacitors -- otherwise the frequency will drift. For just receiving FM broadcast, you *might* get by with "stable" ceramic caps, like X7R, since the signals are broad. But try to get NPO if you can.

For the other capacitors, use ones which are physically small. Multilayer ceramic capacitors are smaller than disks.

Get some solder wick, which is a wire braid soaked with flux. To remove components, first remove the solder with the wick, then you can pull the components out without damaging the board. Any beginner's board that won't tolerate removal of parts is crap and shouldn't be on the market.

Roy Lewallen, W7EL

> . . .

All toroid inductors aren't equal, and neither are capacitors.

I routinely build VFOs with no temperature compensation which have about 200 Hz total warmup drift on 40 meters. The trick is to use components which have inherently low temperature coefficients rather than try to make ones with high coefficients compensate each other. Polystyrene capacitors have a fairly high temperature coefficient, but it's in the opposite direction than a typical poor inductor. Sometimes people get lucky and the combination works ok, but often they don't and it doesn't.

The other thing you have to do is design your oscillator so that its frequency depends almost solely on the tank components and not the active device.

I found that good quality NPO ceramic capacitors have the lowest temperature coefficient of any commonly available parts, and inductors wound on type 6 powdered iron cores were the best. It's the inductor which dominates the drift in my VFOs, and that small amount can easily be compensated if desired by replacing part of the tank C with a capacitor with controlled temperature coefficient.

I described these techniques (except for compensation) in more detail in "An Optimized QRP Transceiver", in August 1980 QST.

At Sea-Pac this year I found out that Wacky Willy's has also moved from its long time location across from the Reedville Cafe.

> Are there any ham radio swap meets coming up?

There's the Salem club swap meet at Rickreall in February, and Sea-Pac at Seaside in June, but no other major local ones I know of. I'm sure that a query on a local repeater would bring full details of any others.

Here's a radio tuner based on a variometer and fixed capacitor. The
variometer housing is a CDROM container; the capacitor is built from
blank CDROMS.

4164. Re: Hi-Q Ceramic Caps?

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-08-30 18:10:03 UTC
From: K7ITM <k7itm@msn.com>
Message-ID: <1156961403.048645.304590@e3g2000cwe.googlegroups.com>
Source record: 10765

Actually, modern ceramic capacitors generally are pretty high Q, though I wonder if the "Hi-Q" may be a trademarked name. The problem, as Roy suggests, is more likely to be temperature stability, and as he says, the 5pF and 15pF parts in the design are the ones to be careful about. I'd guess you will have a very hard time finding 5pF and 15pF capacitors which are NOT either temperature stable (NPO or C0G type) or controlled coefficient (negative or positive temperature coefficient, typically used to compensate for drift in coils...since a coil typically expands with increased temperature, its inductance goes up, and that can be compensated by a capacitor whose capacitance goes down). The dielectrics which are not stable, like X7R, Y5V and Z5U, are used in high capacitance parts, and looking at a couple manufacturers' data sheets, the smallest value X7R I see is 100pF. If the capacitor is large enough, it may be marked "NPO" or "N220" or something similar to let you know its temperature characteristic.

In the RF part of the circuit, especially, keeping lead lengths very short is important. You don't want the part that's supposed to be a capacitor also include a lot of inductance.

There are ceramic capacitors which are specially designed for use at UHF and microwave frequencies, and maintain very high Q up into GHz frequencies, but you shouldn't need anything like that. Also, be aware that "5pF" is deprecated: modern parts are much more likely to be in the standard "e12" sequence: 1.0, 1.2, 1.5, 1.8, 2.2, 2.7, 3.3, 3.9, 4.7, 5.6, 6.8, 8.2, 10, ... So for the "5pF" you'd use a 4.7pF part (and probably not notice the difference at all).

Another note: I notice the instructions you referenced say to use a form for the source coil that's EXACTLY 8mm diameter. I'm confident that if you use one that's 5/16" diameter, you won't notice the difference. In fact, if you use one that's 1/4" diameter and wind it with 32 turns of close-wound 24 AWG enamelled wire, it's very likely to work just as well. You could also use a 2.2uH commercial RF inductor.

So maybe you were only baring your soul...

Cheers,
Tom

Check out the Tin Ear receiver:

http://www.amqrp.org/kits/tin_ear/TinEar%20Manual.pdf

It uses a plastic drinking straw wrapped with wire and a brass screw
to make a variable inductor that is part of a permeability tuned VFO.

3 FETs 4 NPNs and 1 PNP
1 toroid

It is no longer available as a kit but all the info is there to build
one yourself.

Yes, but he has a point - the original person posted this same request
on a VK board on the 24th, was pointed towards mods.dk, but still
keeps on asking the same question!

I think he wants someone to do it for him........and burn a CD, and
mail it to him.....

Andrew VK3BFA.

Source record: 10774

It looks like there are two problems. One is that you don't have a "clear" input on the 74LS190, and the "clear" on the 74LS192 is used in the circuit. But you can use the "load" input, with the A,B,C,D inputs set to zero to accomplish the same thing. Be sure to think about whether the clear takes place when the input is high or low, and whether the load input behaves the same way.

The other problem, of course, is that the '190 uses a single clock input, and an UP/DOWN selection, instead of separate UP and DOWN clocks. Since this is apparently a school project, you should expect to do a little thinking, and then you will learn more. Try to think of a very simple logic circuit, which has two inputs (up clock and down clock) and two outputs (up/down, and clock) that will accomplish what you need. One thing to be careful about: how long before the clock signal comes must the up/down input on the 74LS190 be stable? That is, if the clock comes just when the up/down signal is changing, the 74LS190 may get confused. "Do I count up, or do I count down?" So you want to make sure the clock comes only after the up/down is stable. What do you do if an UP clock comes at the same time as a DOWN clock? Should that ever happen in the circuit you are building? COULD it ever happen?

If you think about all this, and still have questions, please post again. Most people here won't want to just give you the answer, but will want you to think about it yourself. We are quite willing to give you ideas to get you started thinking, but it's from the thinking that you will really learn.

Cheers,
Tom

4174. Contemporary HV Rectification

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-08-31 19:02:54 UTC
From: MarkAren <markaren10@yahoo.com>
Message-ID: <1157050974.453969.142090@74g2000cwt.googlegroups.com>
Source record: 10775

Hi Guys,

I am just about to start on a 2kV supply for a 4CX250 amp. I have a 750VA 1500V transformer and a couple of 15uF 7.5kV caps.

In the full wave rectifier department I seem to have a few options:

1) A bridge of Microwave oven rectifiers like the NTE517, 15kV PIV, 550mA avg, 200A peak surge

This is by far the simplest and has the same surge capability and 500ma / 1500V is in the same ball park as the 750VA transformer rating.

I assume that a small capacitor across each of the 4 devices would be wise -- any suggestions of value.

2) A string of 3 or 4 1N4508 rectifiers, 3-4kV PIV, 3A avg, 200A peak surge

The standard topology for this seems to be voltage equalizing resistors across each rectifier along with a transient absorbing cap - maybe 10nF.

I am sure I have seen some comments that the resistors may reduce reliability (short of using MELF, most metal film resistors seem to be rated at 300-500v). Are their other easily available higher voltage parts ?

Finally a 1500V sine wave has a peak of 2100V, so 3 x 1kV rectifiers is never going to approach the total avalanche voltage, so why bother with the balancing resistors? Sure, the caps have a more balanced voltage across them if the resistors are included...

This design involves 12 x (rectifier + resistor + cap) which is starting to take up some PCB space where some well insulated posts are all that is required to support 4 microwave oven rectifiers.

All comments appreciated,

Thanks,

Mark

The purpose of Private auctions is just that - private. As in not public.

For example, where I work, we have a yearly "sell off some old computers to
the employees" thing. We have used eBay private auctions for this. Only
our employees can bid - not the general public.

Mark, The 1N4007 or JE125, NTE125 diodes are 10 cents each in groups of 100. Get a bunch of one or the other, see what you can get at 2kv FWB rectifier, less than 1 amp. Power up surge may be a problem. No equalizing R or C. Should be cheep enough to run several in each leg of the FWB to see what you can get. I seem to remember that the equalizing R and C has been decided not needed.

Are you tired of buying or building amateur radio equipment? Perhaps putting up an antenna isn't fun anymore. Maybe straining for DX is taking too much effort. Well don't despair - there is an alternative.

You need to consider becoming one of the "next generation" hams. Communicate around the world using your computer and special "radio" software. Traditional VoIP programs like eQSO, Echolink and Skype don't make you feel like a "real ham". You need to take the next step and use the Virtual Ionosphere and the CQ100 Transceiver. Call CQ, twiddle the knobs, send CW and RTTY, use ham lingo and make contacts around the world. However, you will need a ham ticket and $89 (after the trial period) in order to use this next generation "radio".

Full details at www.qsonet.com

Geez - I hope this isn't a glimpse of the future. I think I'll just keep building stuff and be a "relic" ham

Hello OM,
I have build the MRX-40 form a kit many years ago. It
work fine but ...
Now I would like to make a small modification to this receiver.
I would like to replace the tuning capacitor with some kind of diode.
I manage to add a small potentiometer with the shaft getting outside
and I remove the initial capacitor. Now I wonder how and what kind of
diode I could use. I dont have also any idea about what to expect in
the
range of tuning.
May be someone else had the same idea

Any help is will be greatly appraciate.
Happy day

Has anyone here used Superspice ?

I am looking for some information regarding setting up the Simulation parameters to view Phase and Magnitude response for an oscillator circuit (I have opened up the feedback path to enable a signal to be injected through the amp and resonator.

I cannot find what I want in the documentation that came with the software and the company has not replied to my email so I am hoping someone else may be able to help.

Alternately if you know of a shareware or freeware simulator that could I could use that has plenty of forum support ?

The exercise is to work through the book I have on computer simulation "Oscillator Design and Computer Simulation" by Randall Rhea and see if I can get the same results from the examples he gives (the version of his book I have is the very first book sold and the software he used that comes with the book is on an old disk I cannot read).

I have RFSIM99 but cannot see if I can get phase and magnitude responses, I can get magnitude OK but want to have phase information together with this to observe what the relationship is between them at any given point.

Being "green" with regard to simulation, I do not want to purchase a commercial simulator until I have some experience and am confident I will be able to use it to obtain meaningful results.

Thanks in advance.

You might want to consider using LTSpice. Oscillators are documented and the forum support on the Yahoo group is top notch. The program is available from Linear Technology as a free download (with regular updates).

URL is: http://www.linear.com/company/software.jsp

Good luck - Roger

Thanks. That software does the trick. My results are now similar with
the text example.

I downloaded the program and managed to get it running immediately
without documentation. Just need to figure out how to
load the S parameter file for my device now instead of preselecting one
of the models they give in the list.

```
Where is the current limiting going to come from?
-------------------------

The first question that has to be asked in reply is "What does the current
need to be limited to".

The current will automatically be limited to some level by virtue of the
small DC-AC inverter's limited drive capability and the small wall
transformer's limited output capability. 1st order current limiting can be
achieved just by picking the appropriate parts for these two units. However
if a lower current limit is needed then there's a simple solution available
called a "resistor".

Joe

SPICE doesn't know anything about S parameters... you need a linear RF simulator to deal with them (and guess what? Randy Rhea, the guy who wrote your book, was the original designer of Genesys -- that's where all the screenshots in the book come from). With straight SPICE, the traditional approach is to curve-fit a rational polynomial to the S parameters and then use the polynomial directly (most simulators these days have a "Laplace" operator) or systematically turn it into a bunch of controlled sources along with RLCs that mathematically implement the same thing.

I believe that RFSim99 might work for you here...

---Joel Kolstad

Source record: 10789

I don't know exactly what you are trying to get the phase information for, but RFSim99 can certainly display phase information for either or both of its ports; it acts like a vector network analyzer. Just select phase on the graphical display. It's in the pulldown menu on either side of the graph window. Alternatively, you can save the results as an S-parameter file.

With respect to using S-parameters in Spice, you should be able to convert them to the domain that Spice understands with no trouble, at least for discrete frequencies. It's more difficult if you need to come up with a physical model that yields the desired S-parameter performance over a range of frequencies. That's one of the really nice things about RFSim99: you can instantiate a one-port or two-port that uses an arbitrary set of S-parameters versus frequency. (Beware, though, that the two-port model assumes a common terminal between the two ports. And I've had trouble in the past trying to get an ideal transformer give isolation; it seemed to want to assume the non-dotted pins were both grounded. Try for example simulating port 1 feeding the dotted pin of one side, the non-dotted grounded, and the dotted pin of the other side grounded and the non-dotted pin feeding port 2. S11=0, S21 = -208dB.)

It's good to keep in mind that S-parameters and RFSim99 deal only with linear circuits. If your circuit is nonlinear, you should plan to use the time-simulation capability of Spice (or use some other simulator capable of dealing with nonlinear circuits).

Cheers,
Tom

4190. RFSim99 anomalies

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-09-01 20:02:17 UTC
From: K7ITM <k7itm@msn.com>
Message-ID: <1157140937.062925.222160@74g2000cwt.googlegroups.com>
Source record: 10791

Hi all,

Every once in a while I come across an anomaly in RFSim99. I'd be happy if someone could tell me that I'm doing something wrong in the following:

Fire up the simulator. Tools-->Design-->Attenuator. Pi Section, 50R input impedance, 50R output impedance, 10dB attenuation. Simulate. !Current schematic will be overwritten; OK. Now note that the graphics window displays S11 as 2E+31dB.

In the circuit window, edit the values of the two 96.25 ohm resistors; they have apparently been simulated to more decimal places than shown. Just manually enter 96.25 ohms for each. Now the magnitude of S11 and S22 show up as -102.69dB; that seems reasonable. The phases for S11, S12, S21 and S22 are all zero. Now, from the graphics window, File-->Save results as S Parameter File, and save the file in some convenient place, as type S parameter files (*.S2P).

Now delete the resistors from the schematic and instantiate a two-port in their place. In the 2 port properties window that comes up, select "Load File" and load the file you just created from the attenuator simulation. Notice that the phase is 89.994 degrees for each of the S parameters, at each frequency. Or at least that's what I'm getting. Continue on and connect up the schematic and notice that it simulates as 89.994 degrees. Edit the .s2p file with your favorite text editor and notice that it really does have 89.994 degrees in it.

Boy, I wish I could make a frequency-independent 90 degree phase shifter that easily in real life!

More similar fun: create a 10dB 50 ohm attenuator as before and simulate it. Add an 80nH inductor across the top, from port 1 to port 2, and put a 32pF capacitor between the bottom of the two 96.25 ohm resistors (connected together) and ground. Simulating that should give you an S21 that's 0dB at low frequency, smoothly transitioning to -10dB at high frequency, with -5dB at about 120MHz. But S11 and S22 have strange magnitude and phase behaviour. Change the 96.25 ohm resistors to 96.2 ohms, and the S11 and S22 magnitudes behave OK, though their phases are still strange at very low frequencies. Save as an s-parameter file again. For convenience, start another copy of RFSim99 so you can compare the results of a new simulation with the one you just did. In the new window, instantiate a 2-port and load the file you just saved into it. Notice in the file that S11 and S22 angles appear to match the simulation you just saved from; there's no 90 degree phase shift this time. But when you connect ports 1 and 2 to

the 2-port you just placed and simulate it, you find the phase of S11 and of S22 are all messed up. Huh?

Has my copy of RFsim99 gotten corrupted, or do others see this behaviour too?

Cheers,
Tom

Oh, how unadventurous I were. You are correct, the phase selection is in the pull down window.

Thanks for that. I will go back to RFSIM99.

Do you know if they ever made another version of this program or sell a commercial version of it ?

Regards

David

Try VU2UPX's excellent circuit:
http://www.qsl.net/vu2upx/Projects/dc_rx.htm
This uses varicaps for tuning in a NE602 based receiver (although this is
for 20m).

Also
http://www.hanssummers.com/radio/varicap/index.htm
for G0UPL's testing of several common diodes as varicaps.
Red LED's came out top!
Does anyone else have info on using them as varicaps for tuning?

Joel,

Thanks for the link to the interview. I wish the commercial versions of software could be as simple to use as RFSIM99. I was ready to purchase the Gold version of the Superspice simulator and requested some adice from the manufacturer. Having sent 2 emails with no response I have decided to continue using the freeware RFSIM99.

I find RFsim to be really easy to use. I am a novice with regard to simulation but find the editor intuitive to us.

I have downloaded a number of "S-Parameter" files from manufacturers and it is a breeze to use these. I suppose If I could afford a network analyser I could develop a set of S-parameters for any device I use and any bias condition.

Its a shame someone did not develop the program and offer a low cost version with a few more features and support. I find the free version is great and would have been happy to pay something for it.

Regards

David

When using a semiconductor in a transparent package, you should
remember that the ambient light will generate a voltage across a
reverse biased junction.

When using a high resistance potentiometer to generate the tuning
voltage, the voltage generated by the ambient light might upset the
voltage across the diode and hence, the capacitance (and resonant
frequency) varies with the ambient light level.

At least keep the ambient light out of any diode with a transparent
package, when used in a high impedance reverse biased circuit.

And, if the ambient light was from a mains-powered bulb (fluorescents would be worse) there would be a significant amount of 50 or 60 Hz light-flicker energy. This might be sufficient to inject hum into the signal... flicking light modulates junction voltage, which modulates junction capacitance, which modulates the RF oscillator frequency.

So, the LED-varicap-tuned receiver might be both drifty, and hum-prone, if the LED were exposed to light.

>At least keep the ambient light out of any diode with a transparent
>package, when used in a high impedance reverse biased circuit.

Yup. A dab of black paint would be a good idea.

It really depends upon the control board that you have in the unit.

The later EC2002 models were a completely different animal - and had a microprocessor control (pic?) that could be programmed by an external programmer (expensive) - for set-back , specific temperature, etc.

This was used extensively for EC2002 stations used in production / assembly lines (strict control of iron temperature and tip profiles).

This is covered in the EC2002 manuals -- for these later models

Here is the manual on BAMA (you may wish to try mirror site for downloads)
http://bama.sbc.edu/weller.htm

Subject: Re: Weller Tech Sheets
Date: Sun, 11 Jun 2006 02:23:33 GMT

Do you have any tips on fixing a Weller EC-2002-A? It still regulates and heats, but the temperature display is dead. When first turned on it flashes "FFF" for a split second. I think maybe bad filter capacitor or something. Any thoughts on fixing? This is a nice unit I had just bought spare iron and tips for it. Tried another iron, and also measured proper resistance on the thermistor.

4200. Re: Beginner Radio w/o using air variable cap/oscillator parts and drift

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-09-03 00:34:43 UTC
From: WSQT <wsqtradio@ziplip.com>
Message-ID: <1157243682.996972.95950@p79g2000cwp.googlegroups.com>
Source record: 10701

BTW, real air trimmers seem to be far better for temperature stability than normal plastic dielectric trimmers! In an AM broadcast transmitter using a VXO, a plastic trimmer in series with one of two crystals(mixer setup) gave instability and a deep hetrodyne drone that got worse over several days(unattended remote pirate rig) even though the outside temperature was the same.

Replacing it with an air variable trimmer whose plates were apparently cut from two solid pieces of brass mude for utter stability, with no sign of drift over at least a 20 degree temperature change without having to reset it.

For noncritical applications, those little plastic variable caps from car stereos are pretty good. Have not used one in an ultra-critical application in a role giving a lot of control over frequency, but when I used one in the 2004 rig to shift a crystal maybe 2KHZ out of 16MHZ, it didn't seem to drift.

Of course, a VXO(pulled crystal) is a hell of a lot more stable than any VFO! A VXO and a similar but not the same frequency fixed crystal can give a suprisng tuning range with stability. Put in a crystal oven or even a heated/air conditioned room it would leave little to be desired in stability.

For a VFO for any application, the better your parts, the better your results. Wind coil on "air" or unity permeability cores such as wood or ceramic, and epoxy the windings in place. Blow on an oscillator's coil while listening to the beat note with and without the epoxy, and hear the difference for yourself. Wood cores seem to work fine with the epoxy covering.

With an air-core coil,a good tuning capacitor, and a circut that minimizes active device contribution to drift, you end up with a lot less chasing drift to do. Best active device for any VFO and probably any VXO as well is a JFET. Almost no heat(unlike a tube), and no junctions in the current path to change characteristics with temperature(unlike a bipolar). If you must use a powdered iron core, keep DC out of the windings as changes in the DC current change the permeability opf any ferrite or powered-iron core. Ferrite cores of any type have been named as an especially bad source of drift in oscillators, so don't use modified IF transfomers as tuners in oscillators expected to be stable. They are fine in tuned small-signal amps, just not in oscillators.

In that VXO with the bad trimmer, I got lucky and found the bad part first try, but this is unusual. If you have to track down drift expect

hours of work. That's why it takes less tiem to use the good stuff from the start, unless it takes hours of driving or biking to obtain it, of course.

Bob,

IF you are lucky - you may find someone that has a schematics for this
model.
http://www.repeater-builder.com/astron/astron-index.html

I would suggest that you get a copy of the Astron RS-12 power supply -- it
will be CLOSE.
http://www.repeater-builder.com/astron/astron-rs12a.html

Power supply uses the LM723 regulator IC (the most common for linear power
supplies of this type) AND pass transistors for the current handling --
usually 2N3055 or 2N3771.

Here is the 1996 DIY web article that spells out "how they work"
http://www.seits.org/features/pwrsup.htm

Repairing a linear power supply (education, tech sheets, troubleshooting) --
there are over 25 web pages here for any DIY of Astron, Pyramid, TrippLite,
etc.

Well, after looking at a few datasheets, plus a nice Yugoslavian
website
(http://mikroelektronika.co.yu/english/product/books/rrbook/chapter4/chapter4a.htm
), I've come up with this circuit.

http://i9.photobucket.com/albums/a77/Rover_Wow/AMFM.png

So, how is it? Think it holds water? And how much would the budget be?

(And yes, I've already checked the voltages, and it works in a range
from 4.5-6.0V.)

Bob,

BTW, the LM723 will likely be soldered to the regulator PC board inside of the Pyramid.

1. Carefully desolder the part (solder wick works best). NOTE, the orientation of pin 1 on the PC board. The IC should have a notch for that side OR a dot above pin 1 on the plastic top molding.
Dave Metz discusses this in the article -- I bookmarked in earlier message for you (read this)

2. When you working with the LM723 regulator IC assure the large electrolytic capacitors are DISCHARGED before removing OR inserting in the socket (good way to destroy a perfectly good LM723).

Source record: 10713

For Sale: HP3586B Frequency selective level meter VLF receiver

This unit has the high stability oscillator and is excellent condition. No dents, no scratches, and no dust inside whatsoever. I believe it was rack mounted at an environmentally controlled site and seldom used. I don't have the feet and the small blank panels (where the rack ears normally go) but these are common size. This unit works fantastic and has a new NICAD memory battery installed. I replaced one of the jacks in front with a BNC (easily reversed mod that screwed in). I also put a nice black anodized aluminum spinner knob on the VFO shaft encoder for ease of tuning. It makes for a very sensitive VLF receiver and can measure extremely low levels with great accuracy. By the way, there is an RF output jack on rear which enables you to sweep filters etc.

The service manual is included.

$495 plus shipping from central florida

Description :

HP 3586B Selective Level Meter 3586B: Meets North American Bell requirements, 50Hz to 32.5MHz frequency range with 75ohm unbalanced signal input, 4kHz to 1MHz frequency range with 124ohm balanced signal input, 4kHz to 1MHz frequency range with 135ohm balanced Input

I am interested in the origins and purpose of the "IRE (Institute of Radio Engineers) Standard Dummy Antenna," as used during the alignment of radio receivers.

I first came across this circuit in some old Hallicrafter's documentation, which described the alignment of a particular radio. The "IRE Standard Dummy Antenna" consists of four components--- a 200pf cap in series with a 20 uH inductor, which links the signal generator to the receiver's antenna input. A 400 pF cap in series with a 400 ohm resistor is connected in parallel with (shunts)the inductor.

I gather that this circuit models a wire antenna of some type. Is this true? What is the import of the component values and how were they arrived at? I modeled the circuit in Spice and graphed the transfer and impedance curves but it is not entirely clear to me what benefit there is to using this circuit.

I've also Googled this and found some references here and there, but nothing explains the "why" of it.

Is there anyone who can shed light on this?

Its to match the receiver to the generator.

Or more specifically, it's to present a uniform high impedance
from the generator to the radio. At the time, with the exception
of a few lab grade instruments, signal generator outputs were all
over the map with regards to output impedance. The "dummy antenna"
presented a fairly uniform, and high, impedance to the radio and
kept from detuning the front end while doing an alignment while
connected to a signal generator.

Ahhh, so for the very first time, I finally hear an answer to one of those things that I've scratched my head about for years!

I've often wondered why the literature always says to stick a capacitor inline from the signal generator -- I figured if I had to do this all the time, then why didn't the signal generator maker put one in there? Turns out, usually they do, but it's probably not an impedance match. Still, for most radios I just stick the probe to the antenna and go to town. It's fine for the IF -- enough of it gets past the RF to give me a workable signal. Then for RF I use whatever frequency I need to check/adjust the LO. For final RF adjustments I plug in the antenna and tweak it up on a weak station.

Again, I probably differ from most of you because I work mainly with car radios. I already have a pretty decent antenna at the bench -- some $10 special from Auto Zone -- that does a great job. On a conversion there are no RF adjustments; on a repair/rebuild, I can do every adjustment except one, the one which must be done inside the car anyway -- the antenna trimmer. However even this gets checked -- I've noticed that with my bench antenna, the trimmer usually adjusts toward the "high" end, with the screw fairly loose. So if the trimmer tweaks in this area I'm fine. If it tweaks "tight", or not at all, I'll adjust the slug as needed -- or troubleshoot.

Actually it is rare that I ever have such a problem -- with one exception: the 58-60 T-Bird radios. Even these are just fine, usually, but I've had a number of them whose front ends are way off. I've spent many hours trying to figure out why, and come up with nothing. I've replaced RF caps, checked the range of trimmers, checked resistor tolerances, and basically gone over the circuit with a fine tooth comb. Everything checks perfect, but the alignment is out. So I adjust the tuning slug -- a pretty fair distance --

to bring it in line. I've had a couple that were so far off that I had to tinker with the others as well. It's really fun because those slugs are WAA-AAY up in there, and difficult to reach. You can't do it with a non-ferocious screwdriver, or even a ferocious one -- it's too tight. You have to reach the shaft with needle-nose. In any case, all this fun aside, I can tinker and bring it into line -- but I still wonder why I have to do it in the first place.

I think my next step in this "investigation" is to spend time with the next 58-60 T-Bird I get for conversion. If it's a good radio, when I disassemble I'll measure the tuning slugs, trimmers, fixed coils, etc., and write them down for reference.

Yes, although de-embedding the fixture, mounting pads, etc. can sometimes be
annoying.

Depending on the frequencies you need to cover, there are several inexpensive
"homebrew" network analyzers out there... TAPR has one
(http://www.tapr.org/kits_vna.html), and there's another one kicking around
that's better for lower frequencies.

Yes, the dummy antenna models a wire resonant at 2.something Mc. I suppose that was taken to be more or less typical of the receiver antennas of the 30s. The dummy antenna's most important use is as a standardized load for measuring receiver sensitivity. Terman's Radio Engineer's Handbook has a few paragraphs on this.

If you're just adjusting the RF coils, peaking them up on the antenna normally used would be as good or better. Any sort of loose coupling between the generator and RF coils will get you in the ballpark with most radios.

This doesn't sound right, why would it be desirable "to present a uniform high impedance from the generator to the radio"? The impedance of the "IRE Standard Dummy Antenna" is not exactly what I would call "high" especially on some of the short wave bands, exactly what is a high impedance in this context?

It was my understanding that the purpose of the "IRE Standard Dummy Antenna" was to provide a standard antenna to use for making performance measurements, as well as for alignment at the factory and on the service bench.

As to the exact design of the of the "IRE Standard Dummy Antenna", I understood that it was meant to represent the impedance characteristics a typical antenna that might be used by a radio set owner. This topic has been discussed here before and I seem to vaguely remember that someone may have even dug up the exact nature of the antenna the "IRE Standard Dummy Antenna" was designed to simulate. IIRC if you are only doing MW broadcast band alignments a single capacitor will provide a very good approximation of the "IRE Standard Dummy Antenna" across the MW broadcast band. The coil, resistor and second capacitor are there mainly to provide the desired impedance on the short wave bands where the prototype antenna has resonant effects

There are at least two problems that the "IRE Standard Dummy Antenna" solves, the first being standardized measurements for obtaining

performance specifications, as it is possible for a manufacturer to "improve" his products specifications by using his own specially designed "Dummy Antenna". The second problem is how to align sets in the factory, or on the service bench, when the final users actual antenna system is not available. The problem is that the alignment of the antenna stage of a radio is greatly affected by the impedance of the actual antenna that is used with the radio. The "IRE Standard Dummy Antenna" provides an approximation of what was assumed to be a typical consumer antenna. Of course what you really want to do is align the set with the actual antenna attached that it is used with.

It was a bit more complicated than that. If the station under observation
was using a directional antenna (whether rotatable or switchable), the FCC
had to make sure no changes were made to the antenna in the interval between
the two measurements you have mentioned.

Usually a Selective RF Field Strength Meter which was Cal'd to NIST,
or other Federal Standards, with a HP Spectrum Analyser watching
for significant changes in phase and power levels, during, and after,
original measurments. Usually all it took was,"a knock on the door"
and a Station Inspection to get the "Parties Attention", then if
there was a problem, after that, the FCC Field Agent would return
with a US Marshal in tow, and if that didn't work, it was off to the
IronBar Hotel, for the guy. If it was a vessel, then a USCG Chief PO
or Officer would replace the US Marshal, if he was busy elsewhere.
Nothing like a little Federal Mucsle to Get a bit of attention,
when required.

Me been there, done that.....

Well put, John.
I have understood the purpose of the 'matching network' for years, but
I have been puzzled by the source impedance expected on the generator
side.
I have several RF generators of various vintages in my collection and
most of the older tube ones have most peculiar output attenuators that
would have impedances that vary all over the place depending on the
setting of the output attenuator, frequency and, to some degree, output
cable length. On 'modern' generators, once you cut in 10dB or more of
attenuator, the output inpedance it pretty close to the specified, but
even many of them are quite a low impedance at 0 dB.
Perhaps someone with spice can characterize the output impedance of the
IRE network when fed from a generator of 0 ohm, 50 ohm, 75 ohm and,
say, 200 ohm output impedance.

Neil S.

I built an I.R.E. dummy antenna recently to perform an alignment on a
Hallicrafters S-120. It is cobbled together on a small perfboard with
copper lands around the holes, has a length of coax with a male BNC
connector to go the the sig-gen and a female BNC connector to attach the
sig-gen lead.

I will post a pic on a.b.p.r when I can.

Pete, I was curious about the dummy antenna, too. Some time ago I modeled it and checked the impedance looking back into the output leads with a 50-ohm generator at the source. The results are here:

http://users.tns.net/~bb/dummy.htm

Before I did the model I figured that the dummy antenna was trying to simulate a certain length of wire on shortwave. But you can see that the magnitude of the output impedance (upper plot) is around 400 ohms throughout the shortwave part of the spectrum. Down in the broadcast band the network becomes almost purely capacitive, which is what a short wire will do.

In fact, at 500 and 1000 kHz (the two spots I checked), the dummy impedance is almost exactly that of a wire that runs 15 feet vertically and then 90 feet horizontally over perfectly conducting ground. I imagine they had a 100-foot wire in mind, a figure I think I've seen recommended for BC antenna length in the old days.

So I think the network is intended to be 400 ohms resistive at SW and at BC behave as a 100-foot wire would. I align radios with the network and then at installation I tweak the antenna capacitors, if they are easily accessible, on the actual antenna.

Brian--

Your spice simulation looked familiar...VERY familiar. As it turns out,
I had plotted similar curves and happened to have used Microcap as well!
I was just not sure I understood the relationship between the transfer
function I saw and some kind of physical antenna.

Your comments make sense, though I do have one question: How did you
calculate the impedance of the antenna with the shape and dimensions
that you described?

Nice charts, thanks for doing those.

> So I think the network is intended to be 400 ohms resistive at
> SW and at BC behave as a 100-foot wire would.

Pretty much what I said initially. A uniform high impedance.
As others pointed out the output attenuator of most "service"
grade signal generators at the time was all over the place.

What I find amazing is that what we can do with Spice in a few
minutes was painstakingly done by hand until the they got the
results they desired. Then published as a "cook book" standard
for others to use.

The bottom line was that you could introduce a signal into the
receiver under test without undue de-tuning of the tuned circuits.

Pete, I forgot to mention the reason I believe the IRE dummy antenna tries to look like a 400-ohm resistive load at shortwave instead of a certain length of wire. You can see why here:

http://users.tns.net/~bb/antlen.gif

This is an old RCA chart showing the behavior of an end-fed wire for lengths to 125 feet. It indicates the many resonances and antiresonances a short wire can exhibit. Since the antenna impedance and the resulting performance vary so markedly with wire length, and because it would be unrealistic to expect all listeners to use one particular length, I think the dummy antenna is just intended to roughly match the input impedance of a typical radio. I'm not sure about consumer radios, but old communications receivers all seem to have a specified input impedance of either 300 or 400 ohms.

On the broadcast band, any wire shorter than about 150 feet will look capacitive. It won't exhibit the resonances you see in the chart at shortwave. So even if the wire is shorter than the 100-foot length the dummy antenna seems to model and exhibits a higher capacitive reactance, it won't affect the radio's RF tracking that much. On the broadcast band, most radios seem to use rather loose antenna coupling to minimize mistracking. This allows them to accomodate antennas of various length. There is an interesting discussion about antenna coupling strategies in the Radiotron Designer's Handbook.

Wow, do they still do that? I haven't heard of anyone getting nailed for running illegal power for decades, even though very high power is the accepted norm in some segments of the amateur community. If they did get back to busting hams for running more than 1.5 kW, the QRO crowd would have to QSY to CB (or "freeband" frequencies) where it's safe.

But not to worry, the FCC has its hands full protecting our tender eyes from busted bras.

A fellow ham asked me to help him configure a Globe Linear Amp to his Kenwood TS-520 and antenna tuner. It appears to me that the Globe will not let receive signals pass back to the transceiver. This was proven in the shop while hooking up an antenna directly to the Kenwood then putting the linear in line and loosing the receive signal.

I posted a schematic of the Globe Linear on my web site at http://www.ppinyot.com/HomePage.htm. Click on the top most picture to expand the image. It does not appear to me that there is a return path for reception.

How would one accommodate this linear with a transceiver? Do I need two T/R relays to make this work?

Thanks in advance,
Paul.

Judging from the diagram, yes. There is no receive path through that
amp, you're going to have to bypass it with relays/switches to receive.

At the time that amp was designed, it was unusual for a ham to have a
transceiver. Usually, you had a separate transmitter and receiver. And
you already had a T/R switch or relay to switch the antenna between the
two. (or, you used separate antennas for transmitting and receiving)
So if you bought the Globe Linear, you hooked it between your existing
transmitter and your existing T/R switch and you were in business. Of
course, it doesn't work that way with modern rigs!

Yep.
The amplifier pre-dates "transceivers".

To adapt it to transceiver use you'll need to switch the coax _around_
the amp during receive.

Don't expect to operate QSK. HI!HI!

"72 ohm coax"? hmmmm....

AMERICA IN DANGER of its own out-of-control Bio-Terror:
Is 1984 here? God help us, blinded!
Originally Secret Bio-Aerosols are misused to HARM and Torture in
U.S.A.

Our government needs TORTURE in U.S.? See details
below...
It has your VOTE, support? Abused...

CRITICS (political/social/cultural) are harassed and secretly
persecuted
along with their KIDS in schools/colleges, especially, during
tests/exams
(Think: Guantanamo "stress-positions" in the context of
1984-technologies)

Bio-Aerosols and aerosolized chemicals are used to cause:
- severe colds/coughs turning into bronchitis, eye irritation
- bacterial pneumonia/other pneumonia, shortness of breath
- surges of severe headaches, migraines, dizziness, etc.
- fainting collapses by symptoms-mimicking aerosols
- severe stomach pains (sharp, burning, nausea, etc)
- chest-wall pains, heart-muscle inflammations/trauma, etc.
WORSE:
- heart attacks under cover of second-hand smocking
- car crashes/accidents by Vertigo-causing aerosols
- liver/organ failure by small-dose toxins (trace-less?)
- cancer-causing/facilitating - months-long assasinations
This "Yushchenko syndrom" CAN destabilize NATIONs
Waste, Fraud, Cronism and Abuse in HomeSec/FBI

U.S. mail IS polluted in "anthrax-like" manner to HARM critics
Libraries, airplanes, hotels, offices, buses, trains - all polluted!

A network of Secret Gas-Aerosol Rooms operated in US
(in Philadelphia, Narberth, Lower Merion, PA)
(in Wilmington and Newark, DE)
(in Hampton, Williamsburg and Richmond, VA)
AND ELSEWHERE.... details below...
Bio-aerosols used to hurt and simulate panic attacks, etc.!
Soviets locked critics into nut-houses, now WE do the same!
Symptoms-mimicking aerosols do HARM, weak or ill people.

Full text was at:
http://buyit.philly.com/findit/search/results.jsp?catId=krd_philenqda...

This was a new on-line ad placed in Philadelphia Inquirer and
Philadelphia Daily News on www.philly.com (see full text below)
It was about the secret aerosols rooms in US. One could find it by
searching "secret", say, in the ad section of philly.com.

Democracy can not function effectively without the informed public. As
a former NASA Langley scientist working in the area of nanotechnology
and nanoscale particles, I have been recently exposed to the
establishment of secret gas-aerosol rooms inside of United States, at
least in the Mid-Atlantic region (from Philadelphia to Virginia).
First, the highly irritant aerosols have surfaced at the NASA Langley
Research Center in several safety accidents. Investigations were
blocked, probably, because of lack of Congressional approval for such
financially-lucrative research at NASA. Later, these aerosols had been
encountered outside of NASA in Virginia, Delaware and Pennsylvania
.
This points out to yet another proliferation of originally-sensitive
technologies into domestic American life to hurt and harass people
without a proper oversight and much control. This amounts to torture,
extra-judicial prosecution and authoritarian intimidation tactics. The
use of such irritants and the operations of the secret gas-aerosol
rooms are gross violations of human and constitutional rights of
American citizens and various domestic and international laws.

------------------Full text of an ad from Philadelphia's
philly.com-------------------------
TORTURE IN USA: Secret Aerosol Rooms
US Scientist needs legal help dealing with the secret aerosols rooms
(SARs) operated illegally in Philadelphia area, Newark (DE), Hampton
and Williamsburg (VA). Highly volatile aerosols with and without
bacterial content cause dry cough, airways and eyes irritation, chest
pain and inflammation. FBI and Homeland Security associates are likely
operators of SARs, while collaborators may be hotel staff and

landlords, who get financial/material or other incentives. US citizens
and kids are victims.

Torture is any act by which severe pain, whether physical or
psychological, is intentionally inflicted on a person as a means of
intimidation, deterrence, revenge, punishment, sadism, or information
gathering. At times, medicine and medical practitioners have been drawn
into the ranks of torturers, either to judge what victims can endure,
to apply treatments which will enhance torture, or as torturers in
their own right. http://en.wikipedia.org/wiki/Torture

America in Danger!

It's too bad he didn't think of trying zener diodes. By using zeners, you can choose a wide range of capacitances -- low voltage zeners have the most C and higher voltage zeners have less, high power zeners more than low power ones. I've used them for decades for such things as RIT adjustment. A reverse-biased transistor emitter-base junction is also basically a zener, with typical breakdown voltage of around 5 volts, so this works fine as a varicap when a fairly large amount of C is needed.

Any reverse biased diode will behave like a varicap, although as G0UPL found out, small signal diodes (intentionally) have a very small amount of C. The diodes sold as varicaps are doped to provide a particular and repeatable C-vs-V characteristic, but otherwise are the same as other diodes.

The real problem with using varicaps of any kind for tuning is the relatively high and nonlinear temperature coefficient.

Hello,
I want to know the importance of intermediate frequency in any
receivers. IF was used in Superhet transceivers. My question is why
doesn't anyone use zero IF now a days. What is the problem of brining
the RF signal directly to baseband? Does the IF stage conditions the
incoming signal? What are the advantages of the IF stage?

Just confused. Can anyone throw some light on this?

Thanks.

hello!

radio_rookie wrote:

> ... IF was used in Superhet transceivers.

well, IF __is__ used in superhet receivers... :)

> My question is why
> doesn't anyone use zero IF now a days. ....

In fact, you can very well use zero IF in a receiver: what you get,
doing so, is a "direct conversion", or "synchrodyne", receiver, which
is simple, easy to design and realize, cheap, and yet can offer very
high level performances - as is well known to radio amateurs ;)

But... yes, there's a but, and a price to pay: in a DCR, you put all the
required gain (a hundred of dBs, give or take a few) in the base band
(or audio frequency) chain, and this is bad for noise! Most electronic
devices are sensitive to pressure, and a sound is a pressure wave... you
may end up with something which can be quite a decent microphone! >:)

Moreover, in a DCR it may be rather difficult to implement an effective
AGC, so switching from weak to loud signals may be annoying, and even
dangerous for hearing! Also, it's not easy to obtain a reasonable S-meter...

Last, but not least, a simple DCR is inherently a DSB receiver, lest you
implement it with rather complex mixers - which add much to the circuit
total complexity.

Adding all of this up, a superhet may be a good choice...

Actually, it is fairly common -- it is called direct conversion and it is
very popular for simple rigs.

It is not without issues. Converting down to audio means that you cannot
eliminate the "other sideband". Also, since the RF amp needs to be
broadband, you can only get limited gain, so you end up needing a lot of
gain in the audio stage. This is achievable, but it is a little tricky to
manage oscillations, ringing and the like. In addition, getting narrow
bandwidth at audio is also a little dicey, and you can't have it at RF
unless you tune the RF ... also tricky.

Which is why most receivers these days are still superhets. You can choose
an IF that allows you to manage the bandwidth, and even so, multiple
conversion is pretty popular. Many commercial rigs are triple conversion,
typically with IF's around 60 MHz, 10 MHz and 455 kHz, with a very liberal
interpretation of "around" <g>

..

As I understand it, in order to do SSB via direct conversion, you must use a modern version of the old IQ phasing technique. This requires doing the zero-IF mixdown twice, on two different versions of the signal (with a uniform 90-degree phase shift being applied to one copy of the RF or LO signal). The resulting two baseband outputs are then processed (with a further 90-degree phase shift being applied to one of them) and carefully mixed. This results in reinforcement of the desired sideband and suppression of the other.

The circuitry needed to apply the necessary phase shifts is not trivial (if you want enough accuracy to deliver acceptable opposite-sideband rejection), and is not necessarily simpler or less expensive than the filtering and extra stage of mixing done in a traditional IF-based SSB receiver or transmitter.

These days, of course, you can apply the phase shift by converting the two baseband signals to digital format, and implementing the final 90-degree phase shift via a digital FIR all-pass filter. This of course requires your design to have a pair of high-linearity ADCs, a DSP, and a DAC to reproduce the final (mixed) signal.

The "holy Grail" these days seems to be a direct-from-RF system, in which the RF signal is _directly_ sampled (at a ferociously-high sampling rate), and all of the phase shifts and downconversion and mixing are done digitally. RF-grade ADCs with the necessary linearity and speed aren't particularly inexpensive, especially if you need your system to deliver a very high dynamic range which can work properly even in the presence of strong in-band or near-band interferers.

It is trivial, three stages of all pass using opamps for both the I
and Q paths and sum or difference the result. Using 1% parts and
decent opamps opposite sideband suppression of >45db is easy
and 50db or better attainable. Read Breeds and KK7Bs works.

However to build a good Image reject DCR and a good superhet
is not trivial when you consider shielding and mechanical issues
to get the best results.

This is more reproduceable and works very well.

Usually this technique is the "tailend" of a more conventional
Superhet so the RF detection is done at some low IF rather than
baseband. Typically 12-50khz for that IF. Problem is thes end up
being triple (or more) conversion reciever with the need for better
than average shielding or the birdies are prolific.

4258. Inductance specification

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-09-07 23:11:14 UTC
From: David <websales@orbitcoms.com>
Message-ID: <mG1Mg.25015$rP1.12224@news-server.bigpond.net.au>
Source record: 10659

As I was re-reading Boswick's RF Design book it occurred to me that I may have overlooked something very fundamental.

I often transform components from series to parallel form, and visa versa ,depending on what I am wanting to achieve.

What I have over looked is. What form do manufacturer's state Q and inductance ?

I took a look at a coil manufacturer's specs and they don't explicitly say whether the test circuit was series or parallel. I would assume that the standard would be series form ?

Would someone please advise me which it is ?

Though the Q would be same in either form, the inductance and loading could be slightly different.(ie. If I have assumed series form then when I transform into parallel form and calculate a specific Rp and L it would be incorrect if the inductance and Q in the manufacturer's data were specified in parallel form.)

Hopefully someone can make sense of what I am getting at here.

Thanks in advance

Regards

David

Source record: 10660

The Q should be identical when transformed. Q = Xs/Rs = Rp/Xp. It's true that Xs isn't exactly the same as Xp(*) (and therefore Ls isn't exactly equal to Lp), but for even a poor Q, they're much closer than typical component tolerances or even your ability to measure. Any design requiring this kind of accuracy should be reconsidered.

Of course, a series-parallel conversion is correct only at a single frequency, and the Q also varies with frequency. So such conversions need to be applied with caution.

(*) Xp/Xs = (Q^2 + 1) / Q^2, so the ratio is 1.01 when Q is 10, 1.0001 when Q is 100, etc.

>Just confused. Can anyone throw some light on this?

This can be a HUGE subject, but, since this is "homebrew"
we can 'distill' it to a few things: :-)

1. Ever-present random NOISE in the front end. Can't
escape it. Since the amount of noise voltage
reaching the demodulator can be reduced by the
square-root of relative bandwidth, IF bandpass
filtering can cut down that random noise, yield
a constant selectivity regardless of RF input.

2. Direct conversion to baseband is subject to dynamic
range limitations v. the amount of RF input power
and RF input selectivity. i.e., a very strong signal
well out of the desired RF input range might mess
with the sampler causing intermodulation distortion.

3. Lowest RF input level (which determines the
"sensitivity" specification) requires a very low-
noise sampler to equate to a full superhet with an
IF chain. Samplers are not noise-free. Samplers
must compete on the tenths of microvolts (or less)
noise with conventional active mixers of now to
meet high-sensitivity specifications of today.

4 Software (as in an SDR architecture) is NOT simple
to implement, even in a very fast processor. While
it is easy to change demodulation modes, one needs to
understand the math behind the demodulation process.
If you have the TIME and the smarts, go for it; if
not, it may be months before your project works and
then it may not work very well.

5. Not all RF input signals are AM or derivatives of
that (on-off keying, SSB on HF). For FM or
combination AM-PM as in the "modem" fashion, it
might be much easier to implement via a separate IF

plus separate demodulator per mode.

6. In the beginning (1918 and Ed Armstrong in Paris
right after WW1), vacuum tubes were NOT what one
could call the best, noise-free, or even with much
gain. The superhet form allowed the same selectivity
(via the IF bandpass) at any desired RF input
frequency; that did not exist before the superhet.
Since that was a quantum-level improvement at the
time, it had a mystique about it that caused nearly
all designers to follow the IF chain idea with its
diode or tube "detector" (really a rectifier-mixer).
The math of modulation had been published in 1915
(John R. Carson of AT&T) but had yet to spread. It
was not intuitive to the non-mathematical and so
few designers got "into" possible new ways to mix
and demodulate. With better tubes that came after,
the IF and 2nd IF and even 3rd IF as discretes was
easier to design and make. That lasted until
roughly 1980 or about 6 decades, all superhets
having IF chains in a familiar arrangement. It was
"comfortable." More importantly, it worked.

7. If you want selectable bandpass filtering at all
frequencies, the IF with its input bandpass
filters at most any bandwidth you want is the
easiest to design-in and build. That way you
lop off the signals on either side as close to
the antenna as you can get.

8. Heterodyning (mixing) down to one frequency, the
IF, makes it easier to work and debug with a
semi-direct-conversion system. Especially so if
the desired RF inputs have many bands.

9. On the other hand, if portability, light weight,
and low power drain is a requirement (as in military
field receivers), plus all sorts of demodulation
modes, the SDR or Software Designed Radio is the
thing to do, using samplers, A->D conversion and
demodulation in a processor subsystem. Note: You
combine the front end of a conventional IF with
the processor sub-system replacing the IF back end
and 'detectors' to get the best of both.

There isn't any one simple answer. It is all a trade-off
between what is desired and what you can design and make
and how much you have to build plus your budget. Its all
wonderfully complex to decide and I love it. :-)

Roy,

Thanks for your response. So basically it makes no real practical
difference which way they specify the parameters. The lowest Q inductors
I use have Q >= 30 anyway.

Regards

David

> the RF signal directly to baseband?

> Thanks.

Andy writes:
This is the eighth response to your question. All of the others
are accurate. HOWEVER, there is one technical problem with
a homodyne that outweighs the previous resonses...

The L.O, has to be EXACTLY the same frequency as the incoming
signal to provide proper demodulation......

With a superhet, depending on the modulation, you can be
many Khz in error (for AM) or a few dozen off (for voice SSB).
With homodyne, you may have to process a psuedo-baseband signal which
has frequency components you don't want..... that is a bitch....

In order to achieve the LO to be EXACTLY the same
frequency (phase doesn't matter since you can use I and Q),
it is necessary to achieve frequency lock. That requires a
much higher S/N than a simple superhet with a detector...
So you lose sensitivity. In some systems , you can lock
to a remote carrier, but you aren't really talking about those
methods, I don't. think....

So, the major technical problem is not SIMPLICITY or
BANDWIDTH or NUMBER OF STAGES...,.. it is
how to obtain an LO of the correct frequency.... All the
other problems are simple compared to this.... for most systems...

Andy W4OAH

PS I welcome dissent and would like very much to learn
if anything I have said is in error......

You are right on, here Roy, there aren't very many FCC Field Agents left
who actually have done this type of Enforcment Work, but there are a few.
Also there aren't many Field Agents left who can do the required
Calibration on the required Instruments, either, but there are a few.
Mostly the Field Staff spends its time doing Safety of Life and Property
Interference Work, these days, and filling out the Federal Paperwork
required to keep the few Field Offices left, open.

Me one of the few, who could do the work, but who
isn't there anymore.....

4264. Advice on Oscilloscopes Sought

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-09-08 03:03:43 UTC
From: jawod <jawod@fuse.net>
Message-ID: <1e59a$4500de1b$453d9423$2747@FUSE.NET>

Being relatively new to ham radio, I am considering some form of oscilloscope. I am intrigued by PC-based systems (eg., BitScope Pocket Analyzer)

I've read a few NG posts about used HP scopes and a few negative remarks about PC scopes.

My question:

Given my neophyte status and the likelihood that I would use a scope for anything more the basic / with learning, moderate/ complexity,
... is the PC-based scope a good choice for me?
Cost is under $400, not incl. a $40 analog probe.

John
AB8O

PS, apologies for cross-posting to two groups...just trying to get some good answers!

If you are willing to go the Ebay route, and your budget is in the $400
range, you can pick up a seriously nice analog scope. I have a pair of
Tektronix 2245As in my lab that cost me quite a bit less than that each.
If you really need a DSO then that puts the price up a bit.
If your need is for something small and portable, then some of the newer
stuff is probably the only option, but I doubt you will get the same
level of performance/price.

Welcome to the hobby, BTW! I'm really pleased to see your interest in
getting the test equipment side in motion.
I am QRV on most bands from 160m to 10Gigs, and the majority of my gear
is homebrew. I have been a ham for almost four decades, and over that
time have spent a lot more on test gear than I have on commercial
radios. Having the gear to check out my creations goes a long way to
having the confidence to actually put them on the air and make contacts.

There is an old piece of wisdom that HP can't make a 'scope, and Tek
can't make a spectrum analyser. My experience supports that.

Maybe that doesn't answer your question directly, but I hope that helps
in some way.

I believe that what you said is true, but only for AM. What other kind of modulation requires better frequency accuracy from a direct conversion receiver LO than from a superhet LO? I believe that only a small fraction of today's amateurs are interested in AM reception, but of course it's the bread and butter of the SWL and BCL.

I've build direct conversion receivers for many years. Their simplicity is particularly evident when you compare a transceiver having a direct conversion receiver with one having a superhet receiver -- to be honest, be sure to include all the extra filtering necessary with the superhet. The single biggest disadvantage to DC receivers, in my opinion, is the difficulty of making a good AGC, particularly in conjunction with narrow

audio bandwidth. And they do have their own set of potential problems, such as unintended AM demodulation, the effects of LO leakage and radiation, and the difficulties in making a clean, stable, high gain audio amplifier. But all can be overcome once one understands the causes of the problems. All but perhaps the last one will be present in a digital version, too, so a casually designed and/or built one is likely to be a poor performer.

Pete, I remove temporary items from my web site pretty quickly due to space restrictions. I tried to e-mail the chart to you but got the following reply:

----- The following addresses had permanent fatal errors -----
<hpf@gainbroadband.com>
(reason: 591 your host [216.86.143.7] is blacklisted by bl.spamcop.net. No mail will be accepted)

No more midnight spam for me! Anyway, the chart is back up for a couple more days.

By the way, on the perfboard I used to build my dummy antenna I added a 0.1 uF coupling capacitor between the signal generator input and a second output lead with an alligator clip. This provides a 50-ohm DC-isolated signal for IF alignment. I usually align radio IFs by sweeping a signal at the front end, often just blasting through the RF and mixer stages at 455 kHz. But the alligator clip is handy when I want to drive the mixer grid directly. You can drive the grid with the dummy network, but the 50-ohm source impedance of the direct output ensures that the parallel impedance at the grid doesn't affect the sweep flatness.

Brian

I have turned away from PC based test equipment because my PC changes
every few years and my applications become "Legacy Applications" that
either die or require an expensive upgrade.

The older test equipment still works as good as it ever did. Pick a
readily available scope (EBAY?) and read the specs. Compare it to the
other candidates.

Chances are that a Tektronix 453 with a bright screen will do
everything you want for less than $100 including shipping.
It just gets better from there.

Considering they are now 40 years old and still useful is mind
boggling!

Pick one, buy it, learn it. If it does not meet your expectations you
can usually get something out of it on Ebay & buy another.

I agree, although I'd say this is less of a problem these days than, say, a decade back... if you go with a USB interface there's a good chance the driver will work over the course of a couple major Windows OSes (e.g., Windows XP is largely backwards compatible with drivers back to NT); if test equipment manufacturers started using Ethernet more often, it'd make the equipment more or less usable over more than a decade of OSes.

The other nice thing in recent years is that laptops are now cheap enough (~$500 new) that you can often afford to, e.g., dedicate one to some specialized piece of test equpiment you have indefinitely. Desktops are ridiculously cheap -- ~$250 new in many cases --, but of course bulkier (and no integrated LCD).

> Chances are that a Tektronix 453 with a bright screen will do
> everything you want for less than $100 including shipping.
> It just gets better from there.

Any analog scope has rather limited utility for debugging digital logic. It can certainly be done, but I'd defy you to try to debug, e.g., an I2C or RS-232 exchange that hangs with one.

> Pick one, buy it, learn it. If it does not meet your expectations you
> can usually get something out of it on Ebay & buy another.

This is good advice... those old scopes have pretty much depreciated as much as they're going to, so learning on one is relatively cheap.

that's correct :)
the problem here is that you need a phasing filter offering a constant
(and precise) 90 degrees phase shift all over the receiver band, and
that can be tricky to do...

> These days, of course, you can apply the phase shift by
> converting the two baseband signals to digital format...

well, you're opening doors to digital radio :)
But, AFAIK, the actually attainable dynamics does
not seem to incite enthusiastic greetings... ;)

This is not that hard and there are tricks to do this over very wide
ranges. The easiest is create a fixed 90 degree reference and down
convert it.

Another is use one of the I&Q output DDS chips.

The problem is finding fast A/D with enough bits (more than 16)
and using 32bit processors to grind the data. Those two things
are not easy or cheap.. yet. But we are getting there.

that's true but, imho, there's no meaning in removing the (moderate)
complexities of the typical superhet receiver just to put (trickier)
complexities in quadrature downconverting... apart from part count,
controlling the reciprocal phase in two "identical" converters is in
itself not an easy task, since just a single degree of dephasing is
enough to degrade unwanted sideband rejection.

> ... Those two things
> are not easy or cheap.. yet. But we are getting there.

I'm sure we will get there soon enough, and it may
well be that just a few years will suffice; but, as
for now... they are not easy or cheap! :)

Andy responds

I don't disagree with anything you've said. However , i've
found it a lot easier to make the final frequency adjustments
in a superhet since it can be done at a lower frequency.
Trying to sync up at 915 is more challenging than at 455 khz,
obviously. And for systems like FSK and SSB, you gotta
do it somewhere..... And with FM, since the beat formed
by the carrier depends on the modulation index of the
received signal, getting rid of it can be squirrelly.....

Like youself, I've built both types , both as home projects,
and as commercial products, for a long long time. In the
DC versions, if I use I/Q and combine them to form the
audio, the AGC is the same as with superhet SSB. And I generally
use PIN diodes before the front end for the first AGC stage...
But, that's just my own preference.....

Hey radio rookie,

Thanks for posting this excellent question.
The answers you received have taught me more than a few textbooks have.
Some very good minds have weighed in on your query.

Keep up the good work and welcome to ham radio.

To the respondents, I say "Thanks!" for approaching ideal NG activity!

Makes one proud to be a ham.

Eagle is crippleware, but with lot of library symbols. Any PCB's will be limited to two layers and 100mm by 80mm size.

I also think there is a limitation on the hierarchy of schematic subdrawings.

Go get KiCad. GPL license, no limitations and runs on both Linux and Windooze. You find KiCad on the net for download.

First, go to E-Bay and look for a decent analog scope. As you are referring to Dollars, you are probably in the US so you are better off looking for Tektronix scopes.

I suggest you split your money on a miniVNA and a Tek scope. This is an unbeatable combination!

Search for miniVNA on the net and the E-bay for the scope!.

Cheers

I disagree with trickier vs moderate. For a given level of
performance the two are comparable. The only context is
one may be familiar vs different as in new.

The phase of two converters is pretty easy to maintain, having
done it. However, creative part was down converting the LO
rather than the more critical small signal paths. Since the LO
would only at most require low pass (VFO at 70-124mhz with
fixed IQ generation at 70mhz would give a simple dc-54mhz LO)
to prevent the 70mhz and higher components. If passive DBMs
are used phase shifts from gain and added LCs can be avoided.
Also it's possible to put inline measurement of the resulting LOs
and feed back any phase error (found unneeded) for correction.

To build a superhet (ignore selectivity and overload performance for
the moment) to cover dc-54mhz you need upconversion and then down
conversion to IF and lots of filters along the way with switching.
Then you have the problem of various LOs and carrier osc (SSB/CW)
getting back into previous stages causing undesired tones. The more
conversions the greater the problem and the better shielding must be
to avoid it.

Having built both each has challenges and to do it as a high
performing reciever (or TX) requires a very similar effort even if
the areas where the effort need be applied differ.

The one big difference is that the image reject system is less
hardware between antenna and the baseband and that hardware
is more frequency agile. The best available analog answer is the
KK7B MiniR2 (or R2-PRO), base design uses SBL-1 mixers good

from 1-500mhz making generation of an 90degree LO the only real
work. As you go up in frequency a quadrature splitter will have
both phase and level bandwidth that increases making a
tuneable VHF or UHF IF practical. (FYI: accepable (under 1degree
and under 1db level variation) bandwidth at 14mhz is >1mhz.)

Of course the image reject detector system could exist at any fixed
frequency such as 66 mhz with a fixed LO. Then the upconverter only
needs a conventional LO of 66 to 120mhz still yeilds an RX that tunes
from DC to 54mhz and has few if any adjustments. This would yeild a
Single conversion RX with a VHF IF that is remarkably simple
and needs few filters.

If you take that to the next step using DSP at baseband where it's
cheap (using PS and soundcard) you have a very straightforward
high performing multimode radio. This is the current SDR approach.
When you consider a mainboard with ram, sound and other needed bits
running at 1+ ghz is dirt cheap (found free sometimes) and small this
is achieveable. Especially considering the software is already out
there. Also unused CPU cycles could also do the "glass front pannel"
and manage things like tuning the DDS or PLL.

>> ... Those two things
>> are not easy or cheap.. yet. But we are getting there.
>
>I'm sure we will get there soon enough, and it may
>well be that just a few years will suffice; but, as
>for now... they are not easy or cheap! :)

Actually it's progressing faster than you'd notice. The number of Ham
radios with IF DSP as the detection is considerable. Most of the
upper models of Tentec, Yaesu, Kenwood and others are already
doing it. Also the vendors of the DSP processors do have boards
for proto work to venture into this realm. With more people doing it
and plenty of alreay published work it may be more assembly
of components (be they hardware or software) than
construction.

While this wanders far from the IF question posted it's an example fo
how you can have IFs from baseband through UHF or higher.

This evening the GF noticed that the remote control wasn't working & was hot.
I pulled out the extremely hot AA batteries.
It looks like the spring contact in the remote control, on the negative side had worn away the plastic covering on the side of the battery & shorted the side metal battery casing to the negative contact, thereby causing the overheating.
In my many years of battery dissection, I've never seen the side casing of a battery being positive before!
These were "Golden Power" alkaline batteries, made in China.
They were the original batteries that came with the remote (for a Shaw digital cable box).
Anyone ever seen a positive case AA battery before, or is this a new (dumb) idea?

Images of the same signal may be a source of interference.

>Does the IF stage conditions the incoming signal?

Yes, in many ways. The most significant are amplification
and selectivity.

>What are the advantages of the IF stage?

Less amplification needed at the recieved frequency.
Gain at a frequency removed from the recieved frequency.
Selectivity is easier to obtain at lower frequencies.
Gain control can be applied if needed.

You mentioned FM. I have a general question about the Tayloe mixer. Is it possible to receive NBFM or FSK from VHF with it? I'm a little lost in the question how to use the for outgoing phases or I/Q to demodulate FM. All I found on the Net was doing shortwave SSB demodulation.
Are there other analog switches going higher than the mentioned 70MHz for FST3253 or 74HC4066? Perhaps video switches? What is better: Tayloe 4-phases or a switched mixer with one output only? In the latter case I would need a conventional IF filter after the switching mixer?

If I need a DSP at the baseband doing math with the phases or I/Q I would think of an www.wavefrontsemi.com DSP AL3101/2CG DSP-1K will suffice? Wolud it suffice? It is a little simple DSP mainly for doing FIR - but FAST and with 24-bits including audio AD converters ip to 50KHz. The DSP runs with 50MHz up to 1000 instructions long until it repeats the prog. The nice think is a very low pin-count package and cheap too.

There is maybe a middle way with a device like the www.cypress.com PSoC family of mixed-mode Microcontroller with programmable analog cells. There even exists a PSoC app note describing a heterodyne FSK receiver for 130KHz.

Maybe a www.microchip.com dsPIC is better?

Would it better having the IF not at zero but at a usually higher IF, say 25KHz (remember the NFBM!)?

regards -
Henry

I hate to sound "college professor-y", but you really need to be familiar with the literature.

One of the challenges with anything on the Internet is that anyone can say anything. That is one of the great advantages, too! The problem is, especially in a technical forum like this, you will get responses from folks who don't have a clue but want to sound knowledgable. What is perhaps surprising, is that sometimes, especially on this NG, some of the truly giant minds in the field will also weigh in. Unless you are familiar with who is who, you will have a tough time assessing the responses.

But if you review the books and magazine articles on the subject, and browse the archives of various other forums, you will see that some of the leading experts have posted here. Recognize that they might not sound too different than someone who is simply guessing, and be critical in your analysis of the responses you have received.

I suggest that it still lies in the areas of LC filters, resistor networks and individual transistor (or valve) operation.

Because, although the bulk of our circuit complexity will soon lie in a single DSP chip, the interfaces to that chip, to us at the baseband end and then to the antenna at the RF end, still depend upon traditional electronic (pre-IC) practice.

How, then, can it be possible to issue Ham Radio licences to those who cannot tell one end of a resistor from the other?

How, then, can it ever be possible to issue Ham Radio licences to those of 6 years of age who lack the mathematical capability to understand the evaluation of resistances in parallel?

The answer is, that it cannot be possible, and that licences issued to such people are CB licences, no more, no less.

Syllabi for Ham Radio exams should resort to the traditional subjects of familiarity with elemental electrical and electronic components together with a modernised examination of the ability to write software and understanding of DSP theory.

Someone forgot to take his meds.

It would be nice if my newsreader could pick out an author from the text
for automatic plonking, instead of having to chase behind catching up on
all of his aliases.

4294. What Is Ham Radio?.....The FAQ

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-09-09 14:47:42 UTC
From: "If M3 is the answer, it's a silly question!" <me@privacy.net>
Message-ID: <eduk6e$f94$1@emma.aioe.org>

A necessary preface.....

(It is becoming increasingly difficult to fly the flag for
decency and for civilised behaviour in Radio Hammery. Even
the Usenet newsgroups dedicated to the cause have degenerated
into a hotbed of abusive onslaughts by those who ought to know
better; the Nugatory Numpties who boast of an interest
exceeding 10, 20, 30, 40 or even 50 years and yet who have
proved themselves incapable of even meeting the trivial exam
standards set for 6-year-olds. However, there still exists
the fundamental basis on which Ham Radio is based, and
that will never die. This FAQ ("What Is Ham Radio?") will
be regularly published and will not be shouted or bullied
down. It is important that those of a technical bent, who
are the natural seed-corn of Radio Hammery and who
gravitate towards us to be the real novitiate, can
still find us, (and know that we are still here), their fellows.)

-----ooooo-----

So,.....What is Ham Radio?

Ham Radio is a technical pursuit for those who
are interested in the science of radio wave
propagation and who are also interested in the
way that their radios function. It has a long-standing
tradition of providing a source of engineers who
are born naturals.

Ham Radio awakens in its aficionados a whole-life
fascination with all things technical and gives
an all-abiding curiosity to improve one's scientific
knowledge. It's a great swimming pool, please dive in!

This excitement causes a wish to share the experience
with ones fellow man, and shows itself in the
gentlemanly traditions of Ham Radio.

Radio Hams are in a unique privileged position in that
they can construct and operate their own equipment! No-one
else has this privilege. Users, such as broadcasters,
the po lice and armed farces, CBers and mobile phone
users have to purchase ready-made gear. Manufacturers
are not licensed to operate their gear. Radio Hams
are qualified to design, build and then

operate their own pieces of equipment. They do this
with gusto, and also repair and modify their own
equipment. This is a privilege well worth the effort
to gain, and one to be jealously guarded.

The excitement that drives a Radio Ham starts with
relatively simple technologies at first, perhaps making
his own Wimshurst machine and primary cells. Small pieces
of test equipment follow, possibly multimeters and signal
generators. Then comes receivers and transmitters. It is with
the latter that communication with like-minded technically
motivated people takes off. The scope for technical
development grows with the years
and now encompasses DSP and DDS. There is also a great deal
of excitement in the areas of computer programming to
be learnt and applied.

The technical excitement motivates Radio Hams to compete
with each other to determine who has designed and manufactured
the best-quality station. This competitiveness is found in DXing,
competitions and fox-hunts.

-----OOOOO----

However, beware! A Ham Radio licence is such a
desirable thing to have that there are large
numbers of people who wish to be thought of
as Radio Hams when, in fact, they are nothing
of the kind! Usually such people are a
variation of the CB Radio hobbyist; they buy their
radios off the shelf and send them back to be
repaired; they are not interested in technical discussion
and sneer at those who are; they have no idea how
their radios work inside and have no wish to find out;
they are free with rather silly personal insults.

-----ooooo-----

One infallible way to disambiguate the CB Radio Hobbyist
from the _REAL_ Radio Ham is to solicit their view of the
difference between CB Radio and Ham Radio. A Radio Ham will
perceive Ham Radio to be a technical pursuit and will
perceive CB Radio to be a social communications facility
no different in essence to a land-line telephone or a
GSM mobile in the hands of a 6-year-old. Thus a Radio Ham
could also hold a CB licence safe in the knowledge that
such a licence says no more about him than having a land-line
telephone, whilst continuing to regard Ham Radio as a separate
technical pursuit.

A CB Radio hobbyist, on the other hand, sees no difference between
a Ham Radio licence and a CB Radio licence. To him, they are

sisters-under-the-skin. Wrongly, the CB Radio Hobbyist then tries to classify himself as the equal of the Radio Ham when, in fact, he is nothing of the kind.

Ham Radio is not CB Radio and has no common ground with it! Ham Radio is _THE_ technical pursuit for gentlemen; CB Radio is the operating hobby for those who buy their rigs and equipment off the shelf.

-----ooooo-----

If you are the sort of person who is motivated by a technical interest in how things work; if you took apart malfunctioning clocks, toasters and the like and put them right despite never having seen them working, then a Ham Radio licence is your traditional route! There has never been a shortage of such people, and those who gravitate towards such an interest have always been welcomed into our shacks and their interests fostered. There is not today, nor has there ever been, a need to go out and encourage and press children, children who have never expressed an interest in Ham Radio, to come into our shacks. Such an activity should cause eyebrows to be raised - what normal well-adjusted adults seek the social acquaintance of children?!

-----ooooo-----

Please remember that this FAQ is a _POSITIVE EXHORTATION_ to you to exert yourselves to join our fraternity!

Your advice is taken. But, look thru the thread: there was reasonable
consensus and I recognized some "big hitters".

I didn't mean to suggest that one learns best on the NG. Rather, my
intent was to support and give kudos to those who bring the NG up to a
reasonably high standard: no flames, insults, diversions...you know, the
usual stuff.

Here are some of my "favorite" NG remarks
"Get help"
"You have serious issues"
"What's YOUR mensa number?"
"I spent xx years at xx and xx years building xx and have xx degrees, so
I know what I'm talking about"

As one monitors these NG's, one begins to "smell" the diff between the knowledgeable and the blow-hards. The only problem comes when they are one and the same. Luckily, this is uncommon.

I appreciate your advice, "Professor" :)

I can easily agree that an IF amp's job is to cleanly
and efficiently amplify a specific, modulated, carrier frequency
and to allow for gain control feedback.

But I don't see how "selectivity" should be considered a
function of an IF amp (other than they're not amplifying
what they shouldn't amplify).

It seems easier to think of "selectivity" as a property of
a tuner or several tuner stages.

It's hard for me to think of IF "stages" as improving tuner selectivity
when my homebrew 40m DC recvr seems to be selective enough
so that when I listen to CW the pitch will not change audibly.
The frequency may fluctuate a little, but certainly not enough to
loose a signal, and it does not drift monotonically enough to

worry about (except perhaps as a matter of pride).

The superhet's conversion mixers/filters/amps seem to be considered sub-steps of "IF stages", but I find it easier to think of the mixer/filter steps as "stages of tuners interlaced with IF amplifier stages".

Since the final conversion step may represent a detection, the idea of "selectivity" as being interlaced with IF amps has a more tidy representation in my mind.

Comments, criticisms, corrections, caveats - are always welcome.

this is not selectivity, this is stability. selectivity is filtering
nearby strong signals, which direct conversion has more trouble with,

especially as they get closer.
the IF allows cheap, narrow, lower freq filters, which will have great
side skirts to remove the nearby
strong signals.

WTF has software and DSP theory got to do with it? Apart from your
egotistical desire to score points that is. Though, on past form, you
don't seem to come out too well when you discuss your theories with
people that do know what they are talking about.

I might suggest that construction of aerials, amplifiers etc., and the
knowledge to predict propagation modes and then utilise that knowledge
to make contacts with people far away is just as valid as knowing one
end of a resistor from the other.

Or a multitude of other reasons why people become radio amateurs given
that this is such a diverse hobby.

Steve.

>what they shouldn't amplify).

First that last is the central description of what an IF should do.
And the word that defines what should or should not be amplified is
selectivity (or bandwidth).

That come from the former use of distributed selectivity in IF stages,
AKA those old IF cans. Since stages were coupled with tuned circuits
it was possible to add both gain and selectivity. However in modern
designs the IF is preceeded by a crystal filter giving lumped
selectivity. In the end the when people talk about an IF, gain, gain
control and selectivity are central parameters of that circuit block.

>It seems easier to think of "selectivity" as a property of
>a tuner or several tuner stages.

Usually image rejection is perfomed there. Selectivity as in 3khz
bandwidth would be difficult to do at 50mhz!

>It's hard for me to think of IF "stages" as improving tuner selectivity
>when my homebrew 40m DC recvr seems to be selective enough
>so that when I listen to CW the pitch will not change audibly.
>The frequency may fluctuate a little, but certainly not enough to
>loose a signal, and it does not drift monotonically enough to
>worry about (except perhaps as a matter of pride).

DC gets its slectivity at baseband using bandpass or peaking filters.
Also if it's not a image reject design it sees images making it's
selectivity effectively twice the bandpass filters width.

Example of DC at 7.1mhz... if the desired signal is 7.1 and
offending signals at 7.101 and 7.099 what do you hear?
That is where selectivity is important.

Drift is a seperate issue and with care very managable.

>The superhet's conversion mixers/filters/amps seem to be
>considered sub-steps of "IF stages", but I find it easier to
>think of the mixer/filter steps as "stages of tuners interlaced
>with IF amplifier stages".

I'd prefer to not hear that. It muddies the functional description of
what the stage does. It is better to think of RF, Mixer, IF and
detector as distinct systems with functional goals even though the
raw parts used could be very similar.

You use "tuners" in ways that are better described with different and
more specific terms.

For example a tuned circuits at 14.000mhz even with very good Q
will be broad compared to the desired signal. In fact it's barely
narrow enough if the IF is 455khz to suppress the images (lo at
13.545 and image at 13.090). However, at an IF of 455khz with
four tuned circuits of decent Q will give enough selectivity for an
AM signal but marginal for close spaced SSB signals.

>Since the final conversion step may represent a detection,
>the idea of "selectivity" as being interlaced with IF amps
>has a more tidy representation in my mind.

Valid and very traditional designs were exactly that. However
consider lumped gain used with crystal filters. Same effect
very different looking. Lumped vs distributed selctivity
and the same for gain.

Old tube designs would have multiple IF stages at moderate
gain with with multiple tuned circuits for selectivity.

Current solid state would use a ceramic or crystal filter
with lumped gain in the form of an IC or two following.

Both could be designed to provide the exact same gain
and slectivity profiles yet their topology is different. In the
we can use the same terms to talk about both as black boxes
but differing terms when discussing the content.

Good advice Steve. There are even people who buy s/h homebrew equipment (eg
a QRP radio) at rallies and probably take great delight in using it.

One traditional area that I did not mention, but perhaps should
have done, was the tradition of gentlemanly conduct, a tradition
that is seen to be lacking in _ALL_ those who have responded
to this thread.

All have responded as Childish Broadcasters (CBers) with
gratuitous and infantile personal remarks.

Shame on you all. You do nothing for the PR of Ham Radio.

I tend to think of "stability" more in terms of random fluctuations.
Instability may or may not effect selectivity. As long as my desired
selection remains decipherable, I would say that selectivity has
been accomplished regardless of whether there's any kind of instabilty.

Filtering strong nearby signals seems more about "exclusivity"
than "selectivity". I would rather say that IF stages maintain
selectivity while they are excluding undesired mixing products
and other signals.

As long as a recvr includes my desired frequency and it
does not drift out of my receiver's bandwidth requiring
me to retune, then I would say that the recvr is maintaining
selectivity even if I get *more* than what I want.

Considering your past form and your obvious desire to create argument, I think that all who have so far responded have done so in a measured and reasonable way. It seems that you are the odd one out (again).

You have not told me the difference between one end of a resistor and the other despite my polite, earnest, request for more information. To ignore a straightforward question like this is, IMO, very ungentlemanly and against the spirit of amateur radio - especially as you introduced the subject.
>
> All have responded as Childish Broadcasters (CBers) with

Nothing childish about my question at all. Nothing gratuitous either. You as the "know it all" of amateur radio make rash statements then fall back to slagging off everyone who replies by abuse.
>
> Shame on you all. You do nothing for the PR of Ham Radio.
>

And what exactly is your input to the PR of amateur radio? Oh Sorry!, I forgot that you don't like to answer questions about your rash statements... I must have been having a Childish Broadcaster moment.

Steve

I would say as long as the desired baseband signal remains within
the received bandwidth, selectivity has been accomplished.

I agree DC receivers tend to have poor resolution, but this
cannot be corrected by filtering the baseband signal by sending
it through a parametric audio equalizer. Any selectivity of
basebands has to be accomplished before detection. I'm sure
that's not what you meant- but what you said could be interpreted
that way. If I wanted 7.101 I wouldn't detect first and then
try to filter out 7.101 and 7.099.

I agree some DC receivers seem like Michaelangelo trying
to scuplt David with a sledge hammer. You may still receive
the message but it will be impressionistic and so contain
many other messages.

> four tuned circuits of decent Q will give enough selectivity for an
> AM signal but marginal for close spaced SSB signals.

Q loses meaning when the desired frequency does not lie within
the relevant bandwidth. A tuned component can have a very high
Q and yet be very totally unselective of a desired frequency.

What you are talking about is not what I would call selectivity.
I would call it "exclusivity" since it is more about excluding
than about selecting. I can acknowledge that if the exclusions
aren't done correctly at any point in the chain then selectivity
could be be lost.

For me the difference between selectivity and exclusivity
seem alot like the difference between accuracy and precision.
I can be very precise but inaccurate at the same time,
I can be very accurate but imprecise at the same time.
So I find it easier to think that IF stages are more about
precision (exclusivity) than about accuracy (selectivity).

But I quibble and realize "selectivity" is often used
to mean both accuracy and precision. It just seems to
me that IF stages are more about precision than about
accuracy.

ok, call these things whatever you want, but you are making up new names
for existing specs.
I have never seen an 'exclusivity' db rating for a radio, and your
desired signal remaining in the passband has little to do with selectivity:
try listening to a weak signal next to a SW broadcaster, then you find
selectivity. It is invisible until you need it.

<end>

I've seen many Alkaline batteries with the outside casing connected to
the 'tit' on top as the positive and the bottom flat connector was
insulated from the body of the battery. alkaline batteries have
different chemistry from carbon zinc resulting in an inverted
construction. This may actually be the norm, but in the larger sizes
the plastic outer wrap hides the details. Just looked at a DuraCell
"D" and it is of the inverted construction, but the insulation of the
battery bottom (-) terminal from the case of the battery is hidden
under the plastic wrapping.

Since it's the cathode that gets eaten in whichever reaction is used for the
battery type, it might make sense to have the anode as the case.

I could have done with this 25 years ago when I got sent abroad for work for
three of months and came back to find that the transistor radio batteries had
leaked all over one of my (expensive) loudspeakers :-(

You're certainly free to make up interpretations of words any way you choose. But if you want to communicate with others, that is, to have them understand what you're saying and for you to understand what they're saying, it's necessary to use common terms in the way they're widely understood to mean.

In this context, "selectivity" is universally understood to mean the ability to pass some signals and reject others, on the basis of their frequencies, and is quite independent of stability. If this isn't what you mean by "selectivity", you should use some other word or make up a new one and define it, if your objective is to understand and be understood.

In a superhet receiver, most of the selectivity is achieved in the IF stages, for a number of good reasons. One of the reasons is that it prevents off-frequency signals from being amplified to a high level where they can cause intermodulation and other problems. In a direct conversion receiver, all the selectivity (other than relatively broad selectivity from any bandpass filtering ahead of the mixer) is achieved by audio filtering. Properly done, this filtering is near the input of the high gain audio amplifier. Neither is inherently better than the other at the basic job of providing selectivity.

Provided you implement the Tayloe mixer with sufficient baseband
bandwidth (probably about 20 KHz for NBFM), you can mix, say, a 2 meter
FM signal to baseband and demodulate it with an audio discriminator
(some sort of audio frequency to voltage conversion scheme). Mix the
signal to be either exclusively in the upper or lower sideband of the
output. So, for example, a NBFM sig at 146.000 MHz mix with the Tayloe
mixer set to 145.990 MHz and select the upper sideband. The upper or
lower sidebands are, as you probably know, selected by phase shifting
and summing circuits following the Tayloe mixer (implemented in
software in SDRs). Note that SDRs like the Flex-Radio SDR 1000 do not
process incoming signals near 0 Hz anyway, but mix the desired signal
centered around about 11 KHz (I think).

>

The Tayloe mixer is a passive mixer terminated in large capacitors, and
similar performance can be obtained at VHF, UHF and microwaves with two
FET ring mixers driven with quadrature signals and also terminated with
capacitors (that is, no wideband transformer on the mixer outputs, but
capacitors followed by HiZ input differential audio amps). I've done
this with the Peregrine Semiconductor FET mixers.

Only familiar with the dsPIC, though the others sound okay. The dsPIC would work, though its 12 bit A/D doesn't give a lot of dynamic range. Plenty for NBFM though, especially since you can run the signal(s) through a limiter first. For NBFM sixteen bit DSP is sufficient.

Glenn

4321. Basic info needed (longish)

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-09-09 23:31:37 UTC
From: Twiddler <twiddledee@jotjet.net>
Message-ID: <1157844696.952683.201960@i42g2000cwa.googlegroups.com>
Source record: 10622

My brother-in-law was a radio hobbyist and passed away a few months ago. I am helping my sister sell his equipment but I am not very knowledgable and I want to understand more so I can get what it is worth for her. He had no life insurance and she has two children to support. I am worried that I will not describe the equipment fully and not sell it for its true value.

He had several Icom IC-W2A hand-held radios. From what I've read these are fairly old but I think they may be desirable because you can enable them (via the keypad) to scan a wider range of frequences (800 ~ 900+). I think that newer radios have this capability disabled? He also had an AOR AR 1500 that I think has similar unrestricted RX frequencies. Is it legal for me to advertise these exteneded ranges on Ebay listings? There seems to be some secrecy to this kind of thing as I try to research it.

The IC-W2A radios can also be set up as as dual band repeaters. I don't really understand why you would want to do this unless you are providing a repeater service to other people? This seems odd for a hand-held radio.

I have also seen mods for these radios that enable MARS/CAP. He was a very accomplished electronics technician so I would expect he has modified these radios. Besides taking them apart, can I check to see if they have been modified some other way -- maybe tuning to a particual frequency and listening? Again, is it legal to advertise this feature if they have been modified? There doesn't seem to me that there would be much activity on Military Amatuer and Civil Air Patrol but there seems to be a lot of references to MARS/CAP modifications around. He had an Icom IC-207H with a label of "MARS/CAP" on it. It was on his bench and connected to one of five large roof-mounted antennas. I think this was probably one of the radios he used the most. Are there other mods I should look for on it?

He had several GMRS hand helds (Radio Shack and Maxon 210+3) and CB radios (Radio Shack and Uniden). Is there any unique enhancements I should invesigate on these? The Maxon 210+3 radios (he had several of these) also are older models but they push 5 watts. Is that unique to the older radios? Since he had several of this one model I think there must be something unique about them.

He also had a Magnavox D2999 PLL World Receiver. He had modified it for an external (roof mount) antenna. I was thinking about re-connecting the built-in antenna on it before selling. Anything else I should look for on it?

I would appreciate any help or advice you folks can provide. If you have any questions or any tests you can walk me through on these radios I will be glad to give them a shot.

Thanks,
Twiddler

>
> Andrew VK3BFA.

I agree - QsoNet isn't ham radio - it's a software simulator for the "next generation" ham. The list of users is growing as we speak. See http://www.qsonet.com/qbb/memberlist.php They are even advertising on eham.net!! It makes me wonder where we are going with ham radio when "hams" are signing up for something like this.

The "out of the box" radios do not require the construction skills and knowledge necessary for homebrew designs or kits but one still needs an understanding of radio propagation, antenna construction and assembling a station. Experimentation and the satisfaction of making a real contact "over the air" are still part of the experience.

Roger

Your misapplying standard terms to describe RF system behavour.

>I agree DC receivers tend to have poor resolution, but this

Again, if anything ther is no reolution issue unless you applying it
to the frequency dial/display being used to tune in a signal.
An example of poor resolution would be a dial that reads to the
nearest Khz when you need to read to the nearest .01khz (10 cycles).

>cannot be corrected by filtering the baseband signal by sending
>it through a parametric audio equalizer. Any selectivity of

Assume a DC RX. Lo at 7.100 for a CW tone of 1khz what frequency is
the recieved signal? It could be 7.101 or 7.099!

>Q and yet be very totally unselective of a desired frequency.

You do not understand what Q means then.

> A tuned component can have a very high
>Q and yet be very totally unselective of a desired frequency.

Meaningless misstatement!

A tuned component can have a very high
Q and yet be insufficiently selective of a desired frequency.

Would be a correct application.

>What you are talking about is not what I would call selectivity.
>I would call it "exclusivity" since it is more about excluding
>than about selecting. I can acknowledge that if the exclusions
>aren't done correctly at any point in the chain then selectivity

>could be be lost.

Selectivity is measured in bandwidth and DB. These terms are standard
and meaningful. Exclusivity is marking hype at best and never applied
when refering to selectivity.

>For me the difference between selectivity and exclusivity
>seem alot like the difference between accuracy and precision.
>I can be very precise but inaccurate at the same time,
>I can be very accurate but imprecise at the same time.
>So I find it easier to think that IF stages are more about
>precision (exclusivity) than about accuracy (selectivity).

Get a dictionary.

>But I quibble and realize "selectivity" is often used
>to mean both accuracy and precision. It just seems to
>me that IF stages are more about precision than about
>accuracy.

It means neither. Precision is tied to resolution as a concept.
Acccuracy is a matter of calibration or using the same scale.
Selectivity is a matter of what is in or out and the measurements
for radios includes a in or out by how much.

For example a filter with 3khz bandwidth at 6db down with a shape
factor (usually measured at 6 and 60db on the slopes) 2:1 is
6khz wide at -60db. A filter that is 2 khz wide at 6db down with a
shape factor of 3 is also 6khz wide at -60db. However, they will
not sound the same in a given radio nor will the rejection of
undesired signals be the same. This is one of the metrics of
how radios are specified and discussed. To do so any other
way is like specifing the speed of you car in furlongs per fortnight.

A lack of accuracy in language will alway reduce the precision
in the discussion.

Allison

An example of "gratuitous and infantile personal remarks" is the litany
of rudeness coming from the pen of G8IZY. I do not know this
person, and have not dealt with him before,and yet he has
originated a tirade of abusive remarks that are unrelated
to this thread, and unrelated to any behaviour of mine

Gratuitous use of "WTF" is indicative of a _VERY_ childish outburst.

Shame on him...

"WTF has software and DSP theory got to do with it? Apart from your
egotistical desire to score points that is. Though, on past form, you
don't seem to come out too well when you discuss your theories with
people that do know what they are talking about.

-----ooooo-----

Considering your past form and your obvious desire to create argument, I
think that all who have so far responded have done so in a measured and
reasonable way. It seems that you are the odd one out (again).

-----ooooo-----

You have not told me the difference between one end of a resistor and
the other despite my polite, earnest, request for more information. To
ignore a straightforward question like this is, IMO, very ungentlemanly
and against the spirit of amateur radio - especially as you introduced
the subject.

-----00000-----

You as the "know it all" of amateur radio make rash statements then fall back to slagging off everyone who replies by abuse.

-----ooooo-----

And what exactly is your input to the PR of amateur radio? Oh Sorry!, I forgot that you don't like to answer questions about your rash statements... I must have been having a Childish Broadcaster moment. "

It's hard to do anything like this very well by email or newsgroup. I suggest that you contact a local amateur radio club. They should be able to recommend a number of amateurs who are familiar with the equipment and the market for it, who can help you. If you'll tell us your general location, chances are that someone reading this group lives nearby and can recommend a club (or perhaps help in person). Or, you can contact the ARRL, which is the national organization of radio amateurs, who will be glad to help. You can email clubs@arrl.org to find clubs affiliated with the ARRL, or call the ARRL at the number listed at their web site http://www.arrl.org and explain what you need.

G8IZY seems to be asking me why I fail to respond to questions that are put
to me by those whose style is indicative of a childish disposition wishing
to
cause insult. I think the answer to that seeming question is in the question
itself.

Such childish outbursts do nothng for the PR of Ham Radio and should
be ignored.

In addition to the properties and usage of basic discrete components (still very important) and the appreciation of fundamental principles (from an introductory mathematical perspective) of electronics, there is an increasing interest in the use of integrated circuits, especially at low and intermediate signal levels. It is seldom necessary to be an expert at the inner workings of these ICs, but the ability to understand their data sheets and how to employ and interconnect them is a skill that is very useful.

We probably could be tested a little regarding the basic usage of certain kinds of ICs such as opamp, multiplier and DSP types.

I repeat my question word for word;

"Gareth, would you please enlighten me. Apart from reading the value
and, for aesthetic reasons - what is the difference between the two ends?"

That seems like a reasonable question to me. Perhaps you are unable to
answer it because you don't know the answer despite your statement;

> How, then, can it be possible to issue Ham Radio licences
> to those who cannot tell one end of a resistor from the other?

I'm still waiting.

Indeed so. It is the interest and understanding of how devices
of all types function and how to interact with their interfaces
that is the fundamental skill of Ham Radio; a fundamental skill
that is markedly lacking in the CB-like licences issued today,
in particular the M3/CB Fools' Licence of Britland.

When the man-in-the-street can buy an off the shelf radio enabling
him to talk to the whole world, a GSM phone, what difference is
to be perceived from a Radio Ham who seems to do the same -
buys his rigs off-the-shelf and returns them to the shop if needing
repair?

I believe that it is very necessary that we revert the qualifications
for Ham Radio to an understandng of technical matters before
we become perceived as just another consumerist pastime by
the powers-that-be, and our jealously gained privileges are lost.

I feel that I must apologise for the crocodile of immature
and abusive children who dog my every effort on Usenet,
and in particular who have tried to reduce this thread to
an issuance from the cess-pit.

I have been on Usenet since 1994. In that time I have contributed
many articles on my stance towards maintaining the technical and
gentlemanly traditions of Ham Radio. For my pains I have
picked up a series of unpleasant individuals (who illustrate
very well the unacceptable decline in standards?) who resort
to the most grossly offensive and gratuitously insulting outbursts
unrelated to anything that I have ever said or done.

I have _NEVER_ originated any personal attacks on anybody. I am,
however, only human, and have replied on occasion, but only in
defensive indignance.

I have _NEVER_ published any articles intended to annoy people
or to provoke them. Everything that I have published has been
a sincere expression of my stance on a number of areas, liberalism,
republicanism, pacifism, poetry, atheism, anti-plod violence, Ham Radio.

I have never claimed to be omniscient; indeed, when there have areas
in which I have been unable to understand things, I have posted
queries.

I have on several occasions chastised those who use an international
forum such as Usenet to publish infantile insulting tirades. I shall
continue to do so.

IQ phasing detection (AKA image reject mixers) are only necessary
if you want to build a single signal receiver (a good idea).
Many modern DDS chips provide a way to generate perfect quaditure
outputs and by using DSP you can combine the resulting quaditure
af outputs into a single signal. One way to do this on the cheap
is to have a pc sound card sample the two signals.

From the posts I've seen all over the 'net lately,I'd suggest the
expertise is in having pissing contests,and name calling. The "radio"
aspect seems to have been completely forgotten,it's all about how many
different names you can call people on the internet.

You are one lucky guy today Bob. I have a copy the Pyramid Power
Supply already scanned in. I've fixed one or two in my day. The diagram
might be of a slightly different model/size but you can easily use it
to fix your same type supply.

I'll email a copy of my pdf scan to your email address below. If you
don't receive it (about 1MB file size) drop me a note direct at the
email links found on the web page.
www.radiowrench.com/sonic

good luck with your repairs...

I started to respond to your "FAQ" and then changed my mind, but your persistence compels me to respond. I too have been using the 'net for a considerable time, and FidoNet before that.

Thirty-some odd years ago I became interested in becoming a "ham". Several years earlier I had built my first receiver and became interested in electricity at an age when most kids are still trying to get their heads around "See Spot run."

I met an old ham who gave me stacks of "CQ" magazine and ARRL handbooks, most of which I read cover to cover. But, things change and I didn't get my ticket. Eventually I wound up in the Army, working on radar systems (among other things). I am technically inclined and currently work with computer hardware.

I never lost interest in radio and have always been involved, one way or another. Over the last few years I again entertained thoughts about getting my ticket. But, things seem to have changed...and not necessarilly for the better.

It seems to me that qualifications have been relaxed. Is this an attempt to increase participation in an area with declining interest? I don't know. But I do know a few current hams, and I started reading the rec.radio.amateur.homebrew newsgroup, going back to Dec. of 2005.

I am sure that there are still many helpful hams who are good people to know, I've read a number of them in this particular group. Unfortunately, there seems to also be an increasing number of people whose attitudes are repellant...including yours.

You rant about "childish insults", and immediately proceed to insult others in the same manner. You have *your* opinion of what "ham radio" is (or ought to be), and you announce that you are going to jam it down everyone's throats whether they like it or not. Frankly, I really don't see a whole lot of difference between your behaviour and that of some of those dislikeable individuals on the 11 meter band (which you denigrate as a whole with your repeated remarks about "Childish Broadcasters"). In fact, your insistence that your "FAQ" "will not be shouted down" reminds me very much of the individuals who lock down the key and proclaim "Nobody is going to talk over me" and proceed to repeat a bunch of gibberish which serves only to restrict and interfere with civilized conversation.

Though I tend not to participate in the nonsense which occurs in the "normal" portion of 11 meters there are some good people there, as there are in other areas of the spectrum and with whom I communicate. And, despite your assertion to the contrary, there are many of us in and outside of 11 meters who are interested in how radios work, and who build/modify and operate our own equipment.

You also assert that "A Ham Radio licence is such a desirable thing to have...". If it is so "desireable", then why are the standards being relaxed so as to lower the barrier to entry? In your own "FAQ" you you say that the standards are now "trivial" and "set for six-year-olds". What other reason for this could there be besides a declining level of interest?

>they are free with rather silly personal insults.

Pot? Kettle? Black?

> One infallible way to disambiguate the CB Radio Hobbyist from the _REAL_
> Radio Ham is to solicit their view of the difference between CB Radio
> and Ham Radio. A Radio Ham will perceive Ham Radio to be a technical
> pursuit and will perceive CB Radio to be a social communications
> facility

What makes you think that *your* opinion is the only valid opinion? Or, indeed, that it is valid at all?

Strictly a technical pursuit? Surely you jest. Even in the past when technical knowledge and code skills were of greater importance, even "ham" radio was a "social communications facility". The fact that much of the communication may have been technical in nature in no way lessens the "social communication" aspect.

> There is not today, nor has there ever been, a need to go out
> and encourage and press children, children who have never expressed an
> interest in Ham Radio, to come into our shacks. Such an activity should
> cause eyebrows to be raised - what normal well-adjusted adults seek the
> social acquaintance of children?!

What? I'm not even sure how to respond to *this*, except to say that were it not for adults introducing me to various technical pursuits and encouraging me to get involved, and teaching me, I would not have accomplished a fraction of the things I have done over the years.

> Please remember that this FAQ is a _POSITIVE EXHORTATION_ to you to
> exert yourselves to join our fraternity!

If that is your intent, I think you are falling far short of the mark. In fact, you have reduced my interest in obtaining an amateur license practically to zero. Was it Groucho Marx that said "I wouldn't be a member of any club that would have me"? I think I'll take a "pass" on joining *your* "fraternity". You've even got me to thinking that maybe the government(s) should stop wasting money on regulating the amateur bands, open them up to anyone who cares to operate on them, without restrictions, and abandon them them, much as they have done with the "CB" band in the US.

I'll continue to operate my radios but I see little point in expending the effort to get a ham ticket just to encounter the same sort of people that I can run into on 11 meters with no effort at all.

Say, how are you doing with that question of which end of a resistor is which? When you get that worked out, perhaps you'd care to comment on the feasibility of using a tuneable Klystron oscillator to drive a magnetron in a high-power pulsed RF application.

Certainly worth checking out, but I'd be surprised if most people felt that KiCad and EAGLE with "roughly comparable" -- most people would definitely tend to prefer one over the other.

So the phase shifter is NOT for flatten the group delay variance (source is
the Tayloe mixer low-pass)?

Is multiplying I with Q enougth to demodulate FM as in a quadrature
demodulator?
I cannot find a suitable theory page to look for.

>
> The Tayloe mixer is a passive mixer terminated in large capacitors, and

> this with the Peregrine Semiconductor FET mixers.
Thank you for given the link to Peregrine. I read the datasheet. How do you
mix it?
At the moment I prefer the Tayloe mixer because of it's simplicity.
BTW: They have a nice low-power consumption PLL being compatible to
National.

At TI I found nice tinylogic capable of switching like a 4066 down to 500ps
...
Should be possible to run the mixer at 150MHz with it.

How much dynamic range do I need? I thought about 100dB?
If I recall theory I loss 2dB if limiting the signal to remove AM sensitivy.

regards -
Henry

Henry Kiefer wrote:

> So the phase shifter is NOT for flatten the group delay variance (source is
> the Tayloe mixer low-pass)?
If I understand your question correctly, that is true. The IQ output
from the Tayloe mixer (or any IQ mixer) is not upper and lower
sideband. To get those you must do further signal processing, which
usually involves shifting the I and Q channels ninety
degress with respect to each other then summing or subtracting the
channels depending on which sideband you want.

>Is multiplying I with Q enougth to demodulate FM as in a quadrature
>demodulator?
>I cannot find a suitable theory page to look for.

I can't either. The IQ signals multiplied do not make an FM quadrature
detector as the phase does not really shift much over the NBFM
bandwidth. There may be a clever way to extract FM more direcly from
the IQ channels without first detecting a sideband, but I don't know
it.

> Thank you for given the link to Peregrine. I read the datasheet. How do you
> mix it?

Maybe the wrong part? I'm talking about the PE4140 FET ring mixer.
You use two, driven with LOs ninety degress out of phase with respect
to each other.

> At the moment I prefer the Tayloe mixer because of it's simplicity.
> BTW: They have a nice low-power consumption PLL being compatible to
> National.
>
> At TI I found nice tinylogic capable of switching like a 4066 down to 500ps

> Should be possible to run the mixer at 150MHz with it.

Yeah--digital just keeps getting better. Good luck.

> How much dynamic range do I need? I thought about 100dB?
> If I recall theory I loss 2dB if limiting the signal to remove AM sensitivy.techniques,

You need good dynamic range up to the limiter. This can be done with
analog circuits as discussed. After the limiter an A/D converter is
not even needed in theory--a fast-running timer hooked to a digital
port could do the trick. I don't remember any loss by removing AM in
the limiter (since all the the information is contained in the
frequency of the signal), but my theory is in the distant past, back

when FM meant 'funny math'.

Regards,
Glenn

I thought all of the carbon/zinc type batteries had negative cases. The little button on the top is the positive contact for the battery and the other end is essentially flat on most batteries today with some having a stamped bottom and sides in contact.

>the IQ channels without first detecting a sideband, but I don't know
>it.

FM the problem is not responding to amplitude changes but frequency
changes. So any system that can count and measure frequency and
render a pattern based on changing frequency.

Synthetic PLL or simple a software PLL. would do it.
The synthethetic PLL approach means a software oscillator locked
to a varying frequency external signal. The error word generated is
the demodulated signal (apply to D/A or use raw).

>> How much dynamic range do I need? I thought about 100dB?
>> If I recall theory I loss 2dB if limiting the signal to remove AM sensitivy.techniques,

Dynamic range is one of those the more the better but, many things
like noise eat away at it. These days a radio with >80db is good
and >90DB excellent, 100 Db is attainable.

>You need good dynamic range up to the limiter.

You need good dynamic range up to the first selectivity that can
remove offending close in signals.

Then you can limit hard. If you limit before or without adaquate
selectivity you will have intermodulation problems.

> This can be done with
>analog circuits as discussed. After the limiter an A/D converter is
>not even needed in theory--a fast-running timer hooked to a digital
>port could do the trick. I don't remember any loss by removing AM in
>the limiter (since all the the information is contained in the
>frequency of the signal), but my theory is in the distant past, back
>when FM meant 'funny math'.

If the signal is limited then zero crossings are enough. That could
be expressed as 1bit. Your now working in the time/frequency
domain.

That's simple. One end is the goesinto while the other is the
goesouttta unless you hook it up backwards. Then due to great
foresight from the engineers the two ends will automatically swap
functions making the device appear to be bidirectional.

>>
>> Or a multitude of other reasons why people become radio amateurs given
>> that this is such a diverse hobby.
Some of us use it for exercise:
http://www.rogerhalstead.com/ham_files/Tower29.htm

Or the whole project http://www.rogerhalstead.com/ham_files/tower.htm

Although I've been known to use the exercise excuse so I can put up
more antennas. Unfortunatley I have to get the 144 and 440 arrays
down. I already have the mast down to about the 6-meter yagi and have
rebuilt the PST-61 rotator.
>
>Good advice Steve. There are even people who buy s/h homebrew equipment (eg
>a QRP radio) at rallies and probably take great delight in using it.

Lets see... My first home brew rig was about 90 Watts with a pair of
6L6s and a 6AG7 oscillator. Not exactly QRP. The next home brew
projct was a 6C21 HF amp (those things are big) and then a pair of
813s. on HF. Both home brew but a long way from QRP with the exception
of the time when I blew the plate out of a 6C21 and it turned into a
dummy load. I wish I still had that thing if for nothing more than a
conversation piece.

OTOH there is a fair amount of HF QRP around this area (Central
Michigan) with some of the rigs getting fairly sophisticated.

There is a lot of developmet work going on in digital here. The local
system can broadcast the latest RADAR to the laptops of those of us

out storm chasing. APRS (if set up in the car) gives your coordinates back to the EOC. They are working on a portable TV Repeater for a number of reasons in addition to being used for damage assesment.

There's also the networking of packet, repeaters, and the internet.

We have ham stations in both the EOC and the mobile EOC unit. There was talk of adding HF ham stations to both locations.

I've not seen a 4-400 amp on six,, but they are rated to 110 MHz and
the book shows just shy of the legal limit out at 75 MHz.

I don't know how difficult the'd be to neutralize.
Sounds like fun and I think they'd be a better tube for six than
3-400s or 3-500s.

Good luck,

According to Bob May <bobmay@nethere.com>:
> I thought all of the carbon/zinc type batteries had negative cases.

Most did -- but the zinc/carbon individual cells are relatively
rare now. An example of the zinc-carbon ones without a negative case
are the ones which were used to make high voltage batteries (even the 9V
ones) were a wax ring (shaped sort of like a tire) with a zinc plate at
one end and carbon at the other, with the sal-ammoniac (IIRC) in
between. All of the wax rings were joined end to end by melting the
wax, and this connected all the cells in series.

> The
> little button on the top is the positive contact for the battery and the
> other end is essentially flat on most batteries today with some having a
> stamped bottom and sides in contact.

The "little button on the top" was a metal cap over the end of
the central carbon rod which was the actual positive terminal.

However, the Alkaline cells use a different chemistry (I'm not
sure of the details -- but it could be looked up), and the positive
terminal makes the case -- which requires a strange form factor to deal
with all the equipment designed to orient the button properly as a
positive terminal. A standard flashlight would not care, but most
electronic stuff powered by batteries does care, which is why they
continue to shape things so the button is positive, even if it is
connected to the case. The common coin cells are different, because
there were never any of those with the button as positive.

Enjoy,
DoN.

==========
Up to the mid 1970s type 4-400 transmitting valves (tubes) were used in
the UK in Band 1 (approx 45-65 MHz)TV transmitters.
For a 7 kWatts area transmitter there were 7 chassis of 2 valves each.
So they should be excellent for the 50 MHz amateur band.

A very early design can be found in QST March 1967 ,pages 11 - 15.
Titled : Six-Meter Kilowatt with 4-400As or4-125As.

The design involves 2 valves (tubes) in push-pull config.

Although push pull RF Power Amps are nowadays no longer or not
frequently used , I feel it is still interesting reading and might give
some ideas for a homebrew amplifier.

If you can't find the article , I can send you a scanned copy of the 5
pages.

To email me remove the obvious chars from the above address.

Because of phishing, trojans, and other very smart crooks trying to get
into my account, and also because of Paypal complaints that are legion,
there is no way I would link up my main bank account with Paypal. When
I sell something on ebay, I request payment by a money order, when I
buy something on ebay I pay by money order. If the seller wants Paypal
only, I move on to the next listing. I have noticed that more and more
sellers are glad to accept money orders, especially individuals who are
selling their own stuff. I have had no problems with Paypal but there
are just too many really clever scammers working the internet. I
maintain a tiny account in a different bank to handle fees: if I do get
hit by a crook, or by Paypal, the loot would only be about $5.00. In
addition, in Canada, interbank money transfers are safe and inexpensive.

One compelling reason to ONLY fund PayPal with a Credit Card that
will charge-back unauthorized activity and to request a check if you
have more than $20 in your account.
They cannot take what they don't have.

Many years ago, there was an article in QST (I think) that used a pair
of 6C21 radar pulse modulators in Push pull with copper pipe for a
tank circuit. I don't remember what they used for a link but I think
it was just a u-shaped piece of smaller tubing.

That thing would put out today's legal limit with a sneeze. Even more
if you turned the driver on.

Unfortunately 6C21s are big (bout 16" tall), difficult to find, and
expensive. I used to pay $5 USD each.

Doug:

It was the wide use of these tubes (along with others like the 4-250 and 4-1000) in the TV and FM broadcasting industry that made them so plentiful and allowed "used pulls" to be so readily available to hams. Amp designs using them have been around for decades. I just looked in the 1965 ARRL handbook and they have a 4-250 amp for 6 meters. A little homework should turn up many more.

Good luck,

Roger K6XQ

Carl & Jerry were way before my time, but one summer vacation I ran out
of science books in our library's children section. So I got
permission to start reading all the back issues of Pop Electronics on
microfilm. Found lots of cool stuff from back before I was born!

Aarrgg! This is very disappointing! I usually check at least my
values for LC circuits against the LADPAC programs In "Experimental
Methods in RF Design", however. By the way, when I click on
Tools/DesignAttenuator, the schematic that is in the pop-up window for
default 10 dB shows the three resistor values as 71.151 and 96.248.
When I go through the process you did, I get the same results. I
saved the file, and closed and reopened the program. Then, I loaded
the saved 10dBAtten.cct file, and of course got the same -102.69 dB
for S11. Then, I Tuned the values back to 71.151 (which immediately
displayed only 71.15), and tuned the other two to 96.248, (which
displayed 96.25). When I simulated, S11 was now -107 dB!

I just ran the simulation in the LADPAC programs. I first built the
attenuator in Ladbuild, with the resistors rounded off to two decimal
places, and saved the result. In GPLA, I got (after resetting the
scale to -120 dB) S11= -107.3. Then I edited the values to the 3

decimal place values from the original attenuator pop-up window of RFSim99, and got S11=-121.67.

The circuit review feature of GPLA still showed 2 decimal places, rounded off, but saving that version of the attenuator and opening the saved program in Ladbuild showed three decimal place values when clicking on the component.

It's surprising how a couple of thousandths of an ohm can change the S parameters that much.

I'd give a lot to get a copy of a PE article that ran in the (I believe)
58-60 time period regarding a "Game of 21" that was played with a telephone
stepping relay, where it was "you against the computer". I'd like to do a
discrete digital version for my freshman students as a lab project.

Designing the logic is simple; giving out a copy of "how we did it in the
'50s" is priceless.

Hey, thanks for verifying my results, Ted.

It shouldn't be surprising that tiny variations in resistance cause large dB changes. Remember, you're essentially unbalancing a bridge, and looking at the unbalance over 100dB down from full "un-balance." That is, -100dB represents a one part in 10^5 unbalance. 40dB return loss is really quite good, and something you expect only in a pretty carefully controlled setup.

This same sort of thing reaches out and grabs you if you try to make a direct conversion receiver with I and Q paths to balance out the unwanted sideband. You need balance of not worse than ten parts per million to get 100dB sideband suppression, and the components you are using probably have, at BEST, temperature coefficients that can make things worse than that with only a one degree C change.

On the up side, it's exactly this sensitivity that is a strong plus for bridge measurements.

Also, I'm not about to throw RFSim99 out of my toolkit. I just need to be aware of its anomalies, and I'll be very cautious about saving results as an S-parameter file for sure. I see that even an attenuator that's detuned enough that it has only 60dB return loss still gives 90 degree phase shifts! But if I add even 1fF of capacitance across the 71.151 ohm resistor (in the 10dB attenuator, as designed by the attenuator tool), the saved S-parameter file is OK. S12 and S21 are zero degrees (till you get out to really high frequencies). S11 and S22 still show -90 degrees phase, but with a capacitive load (every so slightly capacitive), that seems like the right answer.

By the way, a trick that seems to work to get very accurate component values is to put parts in parallel or series. For example, to simulate a 57.6325nH inductance (ridiculous though it is in practice), invoke a 57.00nH inductance in series with a 632.5pH. Unfortunately, that doesn't work for sub-ohm resistances; milliohms are converted to ohms, and only two decimal places. Double-checking to see that the 57.6325nH inductance simulates correctly, I resonated it with 1nF. I expect resonance at 20.964591MHz, and RFSim with 401 points displayed from 20.965 to 20.967, shows resonance at 20.96460. Changing the simulated inductance by 0.1pH changes the resonance as expected.

Cheers,
Tom

Chemistry lesson for the day:

Be careful what you call the cathode and what you call the anode.
Oxidation ALWAYS occurs at the Anode, and reduction always occurs at
the cathode. The oxidation process results in a chemical losing
electrons, and the reduction process results in a chemical gaining
electrons. (Mnemonics: "oxidation" and "anode" both start with
vowels; "reduction" and "cathode" both start with consonants. "LEO sez
GER": Loss of Electrons is Oxidation. Gain of Electrons is
Reduction.) In a cell delivering power, the ANODE is the NEGATIVE
terminal--the electrons given up in the oxidation chemical reaction
come out there. If you re-charge the cell, the roles of anode and
cathode are reversed. You feed electrons into the negative terminal,
and (with luck) cause a reduction reaction where the chemical at that
pole picks up the electrons and is converted back to what it was when
the battery was freshly charged.

Cheers,
Tom

Sex? I didn't see any reference to sex. I did, however, look at your "blog," etc., and found the answer to my question.

You are not only a moron, but possibly a dangerous psychotic one.

You are going into the "delete without reading" filter.

No, but PayPal has always maintained that the "service" they provide is merely transferring money around, so if you have your bank charge-back something that went through PayPal they *will* dispute the chargeback, and since they can demonstrate that they transferred the money from you to a seller, it's highly unlikely the bank will side with you. As far as the bank is concerned, you sent Paypal some money and they then sent it on to someone else -- unless you can dispute *that*, you're out of luck. The bank doesn't care what "someone else" might have done with the money subsequently.

That being said, PayPal does have their own fraud protection system these days. IMO, dealing with PayPal isn't as safe as buying directly with a credit card, but it's *much* safer than sending a check, money order, etc.

And others don't like homophiles who walk around with a chip on their shoulder and get in everyone's face with their sexual preferences.

Homophilia is the other face of homophobia, and it appears that you suffer from the former malady. Stop looking at everyone else through the prism of your own sexual tension, and stop projecting your fears upon those who are different from you.

Your untrue and fearful cries of "homophobe" are a way of absolving yourself from any responsibility for your own life situation. It is the same thing that blacks do when they overuse the term of "racist," and most of us can see right through that kind of rhetoric no matter who uses it.

You, sir, are playing the blame game, but it doesn't work any longer. It's been worn out long ago. Come up with something real, or else continue to remain a newsgroup fool.

Interesting threads

What about setting up two checking accounts (main and secondary) - the secondary is not linked to anything (overdraft, credit card, savings, etc)

Then keep a small amount in the secondary account ($5 or zero)

Now when some one sends you funds - tell Paypal to send it to the secondary account - when received quickly transfer to your main account.

When you buy thru Palpal -- quickly deposit the required amount in the secondary fund

In both case -- keep track of things until the transaction is complete

Whatta ya think ??

CL -- been doing that for some time now

Problem is that if PayPal tries to take funds out of the account that aren't
there, YOU get charge with NSF, including whatever outrageous fee your bank
charges for NSF checks, and in some states (Idaho comes to mind) you can
actually be charged with a felony.

That could happen on your main account if you aren't careful (joint checking
accounts get really messy with two folks writing checks.)

The secondary account is strictly for Paypal - nothing else.
I said open up a ligit secondary account
I said when you use Paypal to purchase
First transfer the money to your secondary account
Both the money and the account are legit and there waiting for paypal
Of course you must give Paypal your legit account humber for the secondary

account

In other words - I don't want any one (not even my wife - we have separate accounts - keeps things in order) to have access to my Main account.

CL -- works so far. Crossing typing fingers.

What's a credit rating? I haven't used credit for anything for over
20 years. Its been cash up front, or nothing.

You might not care about your credit rating but you will care when a
lien is placed against your home.

And if you were as financially astute as you like to think you are, you
would know that companies and the Government use your credit report to
decide whether they will hire you, give you a security clearance,
determine the rates they charge you...and many other issues that affect
you.

Your credit rating matters.

And I also note that many of those who are bad credit risks deal in
cash only...because it is the only way others will deal with them.

Ironically, your credit rating will actually be "less than perfect" then! :-)

Assuming you don't need a new mortgage any time soon, I suppose you're set.

Do you have a credit card? I know it's possible, but it sure seems like a
pain to live without one these days... especially for things like renting
cars.

I'm hoping it'll soon be illegal for companies to use credit reports in determining whether or not they want to hire people. I'm pretty conservative myself, and I have excellent credit, but making it harder for someone who has bad credit to *get a job* strikes me as absurd: Sure, most people have bad credit due to spending too much on HDTVs or fancy cars or whatever and *not* on baby formula and generic brand blue jeans, but even so, the humanitarian in me says it's better to let these people at least get a job and *try* to get their monetary affairs in order than keeping them jobless and forcing them onto the welfare rolls. From an economic point of view, I'd rather have individual companies bear the purported risk that those with bad credit are supposedly more likely to steal, defraud the employer, etc. than foist all those people onto the taxpayer's teat.

For security clearances looking at credit reports seems reasonable... I'm told that for security clearances at a high enough level the feds go all the way back to your childhood to dig up dirt on you that could be used in a blackmail setup.

For interest rates... well... hard to say; I can see more of a legitimate risk there than with hiring.

I am looking for the following items if someone has any of them for sale.

HP8405A Vector Voltmeter
Sinad Meter or Audio Distortion meter
AC audio voltmeter
RF volt/millivolt meter (to 500 MHz)
VSWR bridge that works up to 500MHz (low power that can be driven from a sig gen)
Tracking generator to suit HP8659B spec analyzer

I am in Australia but will consider purchasing from almost any location.

Thanks

Regards

David Huisman

I came up with this idea to make a tiny antenna tuner. Thought maybe I could remove the wire on a rheostat and rewind it with copper wire so I can make a long wire antenna tuner .

Check a back issues of QST. Someone did it (miracal antenna)
in a construction article.

They wrapped a ferrite toroid (large one) and use the wiper and
bearing from a Wire wound rheostat to select taps on it. I tried it
for a very small Pi tuner and it was decent.

Listen at: http://www.soldersmoke.com

SolderSmoke #32 (September 16, 2006) is now available
on http://www.soldersmoke.com

Topics covered in #32:

-- HW-101 FT101 Hybrid Rigs.
-- BNC and RCA phono connectors.
-- Changing the clutch and oil on an HW-101.
-- Third order intercept rules of thumb.
-- Modular circuit boards.
-- Babbage difference engine.
-- Hardware to crack enigma.
-- Bills video of his DSB rig.
-- MAILBAG: KC2IGJ, G4GOY, WL7M, D. Gaskill, Gary
Beach

Tired of listening to Led Zepplin or NPR on your
I-Pod? Wouldn't you like to be able to carry with
you the kinds of ham radio conversations that you
listen to while in your radio shack?
Mike, KL7R, in Juneau, Alaska, and Bill, M0HBR, in
London, England meet regularly on the ECHOLINK system
to discuss their homebrew radio projects. We are
making them available as PODCASTS.

RSS FEED: You can subscribe to the program, have
them downloaded to your MP-3 player, and listen to
them at your convenience. To subscribe, just cut and
paste this URL into your I-poder (or similar)
software.
http://www.soldersmoke.com/soldersmoke.rss

If you don't have an MP3 player you can just go to the
site below and listen to the latest program (and
earlier editions) using the audio software on your
computer.

http://www.soldersmoke.com

All our programs are available here.

We hope you enjoy the program. Please send us feedback.
